Hydrogen bonds are fundamental chemical interactions that stabilize protein structures, particularly in β sheets, enabling resistance to mechanical stress and environmental extremes. Here, inspired by natural mechanostable proteins with shearing hydrogen bonds, such as titin and silk fibroin, we de novo designed superstable proteins by maximizing hydrogen-bond networks within force-bearing β strands. Using a computational framework combining artificial intelligence-guided structure and sequence design with all-atom molecular dynamics MD simulations, we systematically expanded protein architecture, increasing the number of backbone hydrogen bonds from 4 to 33. The resulting proteins exhibited unfolding forces exceeding 1,000 pN, about 400% stronger than the natural titin immunoglobulin domain, and retained structural integrity after exposure to 150 °C. This molecular-level stability translated directly to macroscopic properties, as demonstrated by the formation of thermally stable hydrogels. Our work introduces a scalable and efficient computational strategy for engineering robust proteins, offering a generalizable approach for the rational design of resilient protein systems for extreme environments.

Hydrogen bonds are fundamental to biomolecular structure, particularly in β sheets, where their collective strength enables proteins to withstand severe mechanical and environmental stress. Nature has evolved a variety of mechanostable proteins—for example, the titin immunoglobulin (Ig) domains, silk fibroin, spider silk β sheets and bacterial adhesion complexes, all of which exploit extensive hydrogen-bond networks within their β -sheet architectures to provide extraordinary stability under stress^{1–10}. Among these, the titin Ig

domain serves as a classic model: it resists hundreds of piconewtons in dynamic force assays by applying force in a shearing force-loading geometry across β strands (Fig. 1a,b)^{11–17}. In this configuration, cooperative hydrogen bonds rupture simultaneously, yielding much greater mechanical resistance than the unzipping geometry, where bonds are broken sequentially and forces are much lower (Fig. 1b). Indeed, proteins or complexes known to exhibit extreme mechanical strength, including SdrG–Fg β and spider silk β sheets, achieve this via shearing of

β -sheet hydrogen bonds, underscoring the central importance of force application geometry in enabling pronounced mechanical resilience. While the principle of hydrogen bonding in a shearing force-loading geometry responsible for high mechanical stability is well established and demonstrated in nature, systematically applying this principle to engineer synthetic proteins with nanonewton-scale stability has remained a substantial challenge.

Classic protein engineering strategies, such as point mutations or cofactor binding, typically yield modest increases in mechanical stability (~ 100 pN), a limited but notable improvement^{18–22}. Fortunately, the emergence of artificial intelligence (AI)-driven models has transformed protein design, enabling precise structural modifications that were previously unattainable^{23–28}. These new tools enable the entire design-and-validation pipeline to be performed in silico: models such as RFdiffusion generate novel backbones, and algorithms such as ProteinMPNN design sequences expected to fold into these structures, followed by high-accuracy structure prediction using AlphaFold2. This suite of tools allows for the rapid exploration of the

vast sequence-structure landscape, accelerating the design of proteins with optimized architectures^{29–34}.

Complementing these design advances, classic molecular dynamics (MD) simulations provide a powerful platform for evaluating protein stability. Techniques such as steered molecular dynamics (SMD) and annealing molecular dynamics (AMD) simulations enable rational screening of candidate proteins^{35–41}. By integrating generative AI-based design and structure models with MD simulations, we established a high-throughput computational pipeline to systematically apply the hydrogen-bond maximization principle on an unprecedented scale.

Using a titin-derived scaffold, we de novo designed a series of proteins (SuperMyo) with progressively extended force-bearing β strands. Our experimental validation revealed a linear increase in unfolding forces with the number of backbone hydrogen bonds, culminating in designs that reach the nanonewton regime. These proteins can serve as building blocks for assembling hyperthermally stable hydrogels that remained intact after autoclaving, demonstrating that molecular-level enhancements effectively translated to macroscopic

material performance. Together, we establish a generalizable and scalable strategy for engineering superstable proteins and introduce a framework for constructing resilient biomolecular materials designed to operate under extreme environmental conditions.

Results

Computational design workflow for engineering superstable proteins with elongated β strands

To design proteins with enhanced mechanical and thermal stability, we selected the human titin I27 domain (I27, the 27th immunoglobulin domain) as our template. Decades of research have shown that I27 resists unfolding primarily through its two terminal β strands^{42,43}, which form four main-chain hydrogen bonds. In dynamic force spectroscopy experiments at rapid pulling speeds of $1,000 \text{ nm s}^{-1}$, this structure generates a characteristic unfolding force of $\sim 200 \text{ pN}$ under applied shear^{44–46}. To improve its stability, we used a three-step AI-driven approach integrated with MD simulations to systematically elongate its force-bearing β strands (Fig. 1c–g):

Structure and sequence generation. Our objective was to design proteins with elongated β strands, incorporating additional hydrogen bonds to enhance stability. We initially extracted the two force-bearing β strands from I27 and used them as input motifs for RFdiffusion to generate protein backbones scaffolded around these β strands (Fig. 1c, left)³¹. RFdiffusion, a diffusion-based generative model for de novo protein backbone design, operates by iteratively denoising random noise into coherent protein folds while conditioning on specified structural motifs, thereby enabling the creation of diverse topologies that integrate the input β strands. This process generated 1,000 diverse protein structures, some of which successfully contained elongated β strands. To refine the initial design pool, approximately half of the generated structures were classified as ‘bad designs’ and discarded because they displayed inadequate strand elongation, unsatisfactory force-loading geometries, backbone entanglements or atomic clashes (Fig. 1c, middle). The remaining rational designs, which exhibited appropriate shearing force-loading geometry and the capacity for enhanced hydrogen bonding, were then subjected to inverse folding using ProteinMPNN³². ProteinMPNN, a graph neural network trained on protein structures, predicts amino acid sequences likely to fold into a given backbone by modelling residue interactions and optimizing for foldability, yielding 400 sequences per structure, each expected to fold into the corresponding target conformation (Fig. 1c, right).

Structure prediction. The generated sequences were then subjected to structure prediction using AF2 and ESMFold (Fig. 1d). Given the large number of sequences ($\sim 200,000$) that required prediction, we initially used ESMFold for its faster prediction capabilities, further accelerated through parallel computing. All predicted structures were ranked according to the pLDDT (predicted local distance difference test) score generated by ESMFold³⁰. The top 1,000 structures were then repredicted using AF2^{29,47}. We further filtered these candidates based on their root-mean-square deviation (r.m.s.d.) from the RFdiffusion-designed backbone structures, excluding those with an r.m.s.d. exceeding 0.2 nm , while also using the pLDDT scores generated by AF2 as a ranking criterion (Supplementary Fig. 1a). This dual-model approach balanced the need for both speed and accuracy in the structure prediction process.

Screening of physical properties. The top 200 protein candidates were screened for physical properties using MD simulations (Supplementary Fig. 1a)^{37,48}. First, SMD simulations were conducted to identify proteins with high unfolding forces^{42,49–52}. Three fast-pulling simulations (1 nm ns^{-1}) were performed to rapidly screen all 200 candidates (Fig. 1e). Based on their unfolding forces, the top 40 designs underwent further, slower-speed SMD simulations (0.1 nm ns^{-1}) to

identify the most mechanically stable candidates in silico. Finally, we screened these candidates for thermal stability through annealing MD simulations⁵³. The top 16 mechanically stable proteins from the SMD simulations were subjected to a $1,000\text{-ns}$ annealing simulation, during which the temperature gradually increased from 0 K to 413 K . We evaluated thermal stability by analysing the r.m.s.d. of the simulation trajectories (Fig. 1f).

This integrated workflow, which combines AI for high-throughput protein generation with MD simulations for physics-based screening, provides a powerful and efficient pipeline to navigate the vast protein design space, ultimately leading from computational hypotheses to experimentally validated proteins (Fig. 1g).

Consequently, we identified three proteins demonstrating outstanding mechanical stability and thermal resilience (Fig. 2a and Supplementary Fig. 1b). They all showed much higher unfolding force compared with I27 in SMD simulations at 0.1 nm ns^{-1} (Fig. 2b). These proteins, inspired by muscle proteins, were named SuperMyo and designated as the A series (Supplementary Table 1).

The three SuperMyo proteins, A25, A218 and A339, were selected for experimental validation based on their superior predicted properties. These proteins, which feature force-bearing β strands capable of forming eight main-chain hydrogen bonds, were successfully expressed and constructed for testing. For accurate comparison, we also included the well-characterized I27 as a benchmark protein, known for its established mechanical stability and a characteristic contour length increment (ΔL_c) of $\sim 28 \text{ nm}$ during unfolding. We quantified their mechanical stability using an atomic force microscopy-based single-molecule force spectroscopy (AFM–SMFS) set-up⁵⁴, pulling at a constant velocity of $1,000 \text{ nm s}^{-1}$ (Fig. 2c). To ensure measurement precision and eliminate non-specific interactions, we used a site-specific covalent immobilization strategy via asparaginyl endopeptidase (AEP)-mediated protein ligation. The glass substrate was first functionalized with a peptide presenting an N-terminal Gly-Leu (GL) recognition motif and an (ELP)₂₀ linker (elastin-like polypeptide). This (ELP)₂₀ linker serves as a spacer to prevent short-range, non-specific surface interactions. Subsequently, the target construct (SdrG-GB1-SuperMyo-GB1), engineered with a C-terminal Asn-Ala-Leu (NAL) tag, was specifically and covalently ligated to the GL motif on the substrate via the AEP enzyme. A similar method was used to conjugate the molecular handle (Fg β -GB1-NAL) to the AFM tip (Supplementary Fig. 2a,b)^{55–57}.

This design utilizes the highly specific and mechanically robust SdrG–Fg β interaction⁹ (known to withstand forces $>2 \text{ nN}$) as a molecular handle, guaranteeing efficient pick-up and total unfolding of single target molecules. Upon tip retraction, the force applied specifically unfolds the SuperMyo protein, generating characteristic sawtooth-like force–extension curves (Fig. 2d). Three peaks, each with a ΔL_c of 18 nm , were observed from unfolding of three unambiguous internal fingerprint GB1s in the system as expected^{58,59}. The red portions of the curves represent the unfolding events of I27, A25, A218 and A339, with ΔL_c values of $27.8 \pm 0.1 \text{ nm}$ (Gaussian mean $\pm$ s.e.m., $n = 324$, 89 amino acids (aa), theoretical $\Delta L_c = 28.2 \text{ nm}$), $44.0 \pm 1.6 \text{ nm}$ ($n = 205$, 122 aa, 44.8 nm), $42.1 \pm 0.2 \text{ nm}$ ($n = 121$, 115 aa, 42.5 nm) and $42.5 \pm 0.04 \text{ nm}$ ($n = 715$, 112 aa, 41.2 nm), respectively (Supplementary Table 1). These values are consistent with the theoretical unfolding lengths of the predicted SuperMyo protein structure, providing validation of their structural design.

Statistical analysis of their unfolding forces (Fig. 2e and Supplementary Table 1) revealed that the most probable unfolding forces for A25, A218 and A339 are $342 \pm 2 \text{ pN}$ (Gaussian mean $\pm$ s.e.m., $n = 205$), $342 \pm 3 \text{ pN}$ ($n = 121$) and $352 \pm 1 \text{ pN}$ ($n = 715$), respectively, under an average loading rate of $\sim 10^4 \text{ pN s}^{-1}$ (Supplementary Table 1). Compared with the $246 \pm 2 \text{ pN}$ ($n = 324$) of I27 under the same pulling speed of $1,000 \text{ nm s}^{-1}$ (ref. 60), all three SuperMyo proteins demonstrated a notable increase in force (40%), confirming the effectiveness of our design strategy.

Fig. 2 | Experimental validation of designed SuperMyos with higher mechanostability. **a**, Titin I27 and three best candidates, SuperMyo A25, A218 and A339, were screened for experimental validation. **b**, SMD simulation results for the four proteins. The average force–distance profile for N- to C-terminal stretching, obtained from three independent SMD simulations, is represented by the black curve. The blue curves indicate the corresponding number of backbone hydrogen bonds within the force-bearing β strands during the unfolding process. **c**, Force spectroscopy experiment set-up: the AFM tip modified with Fg β picks up the fusion protein coated on the substrate through the Fg β -SdrG interaction. The tip retraction will induce protein unfolding. **d**, Representative

force–extension curves of protein unfolding. The red portions of curves (1), (2) and (3) represent the unfolding events of A25, A218 and A339 with characteristic ΔL_c of $\sim 40 \text{ nm}$, respectively. The three 18-nm peaks were from single-molecule fingerprint GBIs. **e**, Statistical analysis of the SuperMyo unfolding forces showed a higher unfolding force than I27 (350 pN versus 246 pN). The red dashed line indicates the Gaussian fit curve. **f**, CD spectrum of A339, with the y-axis representing MRE (mean residue ellipticity), showing the expected signal range (210–230 nm) characteristic of an $\alpha + \beta$ structure. **g**, Comparison of the predicted structure of A339 (left) and the obtained solution NMR structure.

To further validate the structural design, we first performed the circular dichroism (CD) spectroscopy measurement of A339. The CD spectrum exhibited a broad negative peak spanning from approximately 210 nm to 230 nm. This feature is characteristic of a mixed α/β secondary structure, arising from the superposition of negative signals from both β sheets (a minimum around 218 nm) and α helices (minima at $\sim 208 \text{ nm}$ and $\sim 222 \text{ nm}$) (Fig. 2f)⁶¹. Additionally, we obtained the solution NMR structure of A339⁶², which closely aligned with the predicted model, confirming both the $\alpha + \beta$ conformation and the presence of the eight main-chain hydrogen bonds (Fig. 2g and Supplementary Table 2).

Iterative design and validation of SuperMyo for enhanced mechanical stability

Building on the success of the A-series SuperMyo protein, we conducted multiple iterative rounds to further elongate the force-bearing β strands and increase the number of main-chain hydrogen bonds (Supplementary Fig. 1), with the aim of achieving even greater mechanical stability. Five additional series—B, C, D, E and F—were designed following the same protocol, with only the top three candidates from each series selected for experimental validation. In each round, five additional hydrogen bonds were added. For example, the force-bearing β strands of A339 served as the basis for the B series, which added five more hydrogen bonds. This process continued with B series serving as the starting point for the C series, and so on, ultimately culminating in the F series, which featured a total of 33 hydrogen bonds (Fig. 3a, Table 1 and Supplementary Fig. 3).

The highest-performing proteins from each series—A339, B42, C352, D399, E389 and F553—were identified, and exhibited the highest unfolding forces in force spectroscopy experiments (Supplementary Table 1). Three SMD simulations at a constant 0.1 nm ns^{-1} pulling speed yielded average unfolding forces of 1,300, 1,390, 1,618, 1,974, 2,038 and 2,516 pN for the six proteins,

respectively, compared with 996 pN for I27 in silico (Fig. 3b, black curve, Supplementary Fig. 4, Supplementary Table 1 and Supplementary Videos 1–6). Corresponding force-loading rates are detailed in Supplementary Table 1. In these simulations, the unfolding event, marked by the primary force peak, was consistently accompanied by an abrupt drop in the number of backbone hydrogen bonds in the force-bearing β strands (Fig. 3b, blue curve), confirming their cooperative rupture as the source of mechanostability. These results demonstrate a strong correlation between the length of the force-bearing β strands, the number of hydrogen bonds and the unfolding force. We note that the initial hydrogen-bond count in these dynamic simulations is slightly lower than in static structures, particularly for longer β strands, reflecting the breaking and reforming of hydrogen bonds due to thermal motion. It is noted that SMD simulations are conducted at much higher pulling speeds (10^8 nm s^{-1} ; force-loading rate range, $\sim 10^{10}$ – $10^{11} \text{ pN s}^{-1}$) than experimental measurements (10^3 nm s^{-1} , $\sim 10^4$ – 10^5 pN s^{-1}) due to computational constraints⁶³. Consequently, simulated forces are overestimated ($\sim 1,000 \text{ pN}$ for I27 in silico versus $\sim 200 \text{ pN}$ experimentally). Despite this, SMD remains a widely used semiquantitative screening tool for ranking candidate proteins based on relative mechanostability.

The six SuperMyo proteins were successfully expressed. Interestingly, the protein yield appeared to be proportional to the complexity of the design, with the last three proteins yielding below 1 mg per litre of LB medium (Table 1). This limited yield partly influenced the decision to conclude the design iterations at the F series. Nevertheless, the yield for all six proteins was sufficient for single-molecule experiments. Force–extension curves obtained from AFM–SMFS experiments showed distinct unfolding events corresponding to the designed protein structures (Fig. 3c, red curves). Each SuperMyo protein displayed unique ΔL_c values as expected, $42.5 \pm 0.04 \text{ nm}$ for A339 ($n = 715, 112 \text{ aa}$, 41.2 nm), $32.4 \pm 0.1 \text{ nm}$ for B42 ($n = 488, 97 \text{ aa}$, 32.9 nm), $50.8 \pm 0.05 \text{ nm}$

Fig. 3 | Mechanical analysis of SuperMyo protein series. a, Structural representations of the natural I27 domain and the SuperMyo protein series, illustrating the progressive elongation of β strands and the increase in main-chain hydrogen bonds. **b**, Averaged force–extension curves (black) from three SMD simulations for each protein, depicting their unfolding process. The blue curves indicate the corresponding number of backbone hydrogen bonds within the force-bearing β strands during the unfolding process. **c, d**, Representative force–extension curves (c) with the red part from SuperMyo and the

corresponding unfolding force distribution (d), for A339, B42, C352, D399, E389 and F553. **e**, A positive correlation was observed between the unfolding force and the number of hydrogen bonds in the force-bearing β strand of the SuperMyo proteins. **f**, Schematic diagram of the protein-refolding experiment, showing the sequence of unfolding (steps 1–3) as the AFM tip moves away from the substrate, followed by refolding (steps 3–1) as the tip moves back toward the substrate. **g**, Representative successful refolding curves. The refolding curves are offset for clarity.

for C352 ($n = 891$, 144 aa, 51.8 nm), 65.4 ± 0.05 nm for D399 ($n = 658$, 185 aa, 65.6 nm), 69.0 ± 0.1 nm for E389 ($n = 215$, 196 aa, 68.4 nm) and 99.2 ± 0.1 nm for F553 ($n = 317$, 276 aa, 100.9 nm), closely matching the theoretical unfolding lengths predicted based on their sequences and structures (Supplementary Information).

Moreover, the unfolding forces for SuperMyo proteins were markedly higher than those of the natural I27. The most probable unfolding forces for the progressively elongated β -strand SuperMyo proteins were 352 ± 1 pN (gaussian mean $\pm$ s.e.m., $n = 715$), 431 ± 1 pN ($n = 488$), 559 ± 2 pN ($n = 891$), 744 ± 3 pN ($n = 658$), 839 ± 3 pN

Table 1 | Statistical results for SuperMyo proteins in each series

($n = 215$) and $1,050 \pm 6$ pN ($n = 317$), respectively (Fig. 3d, Table 1 and Supplementary Figs. 5–10). These experimental results demonstrate that the protein's unfolding force increases linearly with the length of the force-bearing β -strands and the corresponding number of backbone hydrogen bonds under our experimental condition (Fig. 3e). This observation is noteworthy as it deviates from the behaviour predicted by classic polymer theories, such as De Gennes's model for DNA shearing, which anticipate a force plateau due to edge-fraying effects⁶⁴. We hypothesize that in our system, the rigid β -sandwich architecture constrains the terminal strands, thereby suppressing fraying and allowing the force to be distributed across all hydrogen bonds. This confirms that our design strategy is an effective and precise approach for engineering proteins with enhanced mechanical stability.

Next, we examined the refolding ability of the designed proteins following mechanical unfolding, an essential characteristic of muscle proteins such as titin^{1,60}. To do this, we unfolded the protein without detaching it and allowed the force to return to zero for a 400-ms pause, providing an opportunity for the protein to refold. We then stretched the protein again (Fig. 3f). Observations of unfolding signals after multiple unfolding–refolding cycles (Fig. 3g, red peaks, representative successful refolding events) indicated that the SuperMyo proteins retained reversible folding–unfolding properties. The refolding probability within this process varied among the designs. B42 demonstrated a high refolding probability of ~90%, followed by A339 at a substantial ~40%. Other designs also showed measurable, albeit lower, refolding capacities.

SuperMyo maintains its mechanical function after extreme thermal treatment

Thermal stability is a crucial property of proteins because it indicates their ability to maintain function under extreme temperatures. The Ig domain of titin is known for its relatively high thermal stability, exemplified by the I27 domain, which has a melting temperature (T_m) of ~70 °C⁶⁵. In designing SuperMyo proteins, we also focus on the thermal stability and select candidates during the MD simulation phase that could withstand high temperatures without undergoing structural changes. During the annealing simulation, where the temperature was gradually increased from 0 K to 413 K, we used r.m.s.d. as a vital metric to monitor protein structural changes and select the six representative proteins (Fig. 4a, Supplementary Fig. 11 and Supplementary Videos 7–12)⁶⁶.

Considering later measurement and application at the ensemble level, we focused on the first three series of SuperMyo proteins, A339, B42, C352, with a high yield for in-depth analysis. In the simulations, they all exhibited minimal changes in their main secondary structures, making them the most stable candidates in their respective series (Supplementary Videos 7–9). Moreover, we experimentally tested the thermal stability of these proteins by temperature-dependent CD. The CD spectra, recorded during heating from 25 °C to 92 °C, showed only minimal changes for all three proteins, indicating their secondary

structures remained intact (Fig. 3b). A detailed analysis of the signal at 195 nm, a key indicator for β -sheet content⁶¹, further confirmed the absence of unfolding during the temperature ramp (Fig. 4b, inset). Given that the overall spectral shape was preserved, we determined that the T_m for all three proteins exceeds 90 °C, highlighting their remarkable thermal stability. These experiments demonstrated that these three SuperMyo proteins possess excellent thermal stability, validating their design for enhanced thermal stability.

More importantly, to evaluate whether the SuperMyo proteins could retain their mechanical function after extreme thermal treatment, we subjected them to a rigorous heating cycle test. In this test, the proteins were first incubated at 121 °C, a temperature commonly used in autoclaves, and then immediately frozen using liquid nitrogen (Fig. 4c and Supplementary Fig. 12). The robustness of SuperMyo proteins was evident at the macroscopic level: while the wild-type I27 precipitated, SuperMyo protein solutions remained clear. Ultraviolet–visible (UV–vis) spectroscopy further revealed that the proteins retained their structural integrity, as indicated by consistent 280-nm absorbance (Fig. 3d,e).

Next, we tested their mechanical functionality after these extreme thermal treatments. The proteins were immobilized in the AFM–SMFS system using an enzyme-catalysed method, similar to the previous set-up but with slight modifications (Fig. 4f and Supplementary Fig. 2c). Due to the harsh conditions, the previously used pulling handling protein SdrG could not survive, so only the SuperMyo protein was treated and linked with SdrG via enzymatic ligation. Remarkably, the unfolding experiments showed characteristic SuperMyo unfolding signals with similarly high forces, indicating that the proteins maintained their mechanical functionality even after repeated thermal cycling (Fig. 4g, red line and Fig. 4h, red bin).

In addition to the heating cycle, we tested the thermal stability of the proteins at the highest temperature before carbonization, heating them to 150 °C for 1 h and then cooling them to room temperature. AFM–SMFS measurements still showed that the proteins retained their functionality (Fig. 4g, green line, Fig. 4h, green bin, Supplementary Figs. 12–14 and Supplementary Table 3). Furthermore, their CD spectra remained consistent with those recorded before treatment (Supplementary Fig. 13). Consequently, the SuperMyo proteins demonstrated excellent thermal stability, maintaining their mechanical properties even after exposure to extreme temperatures.

Building on the established application of building protein-based materials^{67,68}, our SuperMyo proteins offer promising building blocks for hydrogels with robust thermal stability^{69,70}. To demonstrate this, we used the classic SpyTag–SpyCatcher system to create protein hydrogels by reacting SpyTag–POI–SpyTag–POI–SpyTag constructs with a four-armed polyethylene glycol (PEG) crosslinker fused with SpyCatcher^{71–73}. Using I27, A339 and B42, we successfully formed hydrogels (Fig. 5a). Rheological experiments confirmed the characteristic viscoelastic properties of a protein-based hydrogel. Strain sweeps showed the storage modulus (G') and loss modulus (G'') of the hydrogels, demonstrating their successful formation (Fig. 5b). In thermal stability tests, I27 hydrogels precipitated and denatured at 80 °C, while A339 and B42 hydrogels remained transparent and gel-like even after heating to 121 °C (Fig. 5c). Real-time heating rheological experiments highlighted their distinct behaviours: I27 hydrogels showed a sharp increase in storage modulus near 80 °C, indicating denaturation, whereas A339 and B42 hydrogels maintained stable storage modulus, reflecting their superior thermal stability (Fig. 5d). Thus, A339 and B42 hydrogels remained intact during 121 °C heating, demonstrating their suitability for standard sterilization processes and potential for medical applications requiring autoclaving.

Discussion

In this study, we demonstrated that the systematic application of a well-established chemical principle, the maximization of hydrogen

bonds in a shear geometry, can be used to de novo design proteins with enhanced mechanostability. By systematically elongating the force-bearing β strands of a titin I27-derived scaffold, we engineered a series of SuperMyo proteins with progressively enhanced mechanical resilience. Our results reveal a positive correlation between mechanical stability and the number of backbone hydrogen bonds, culminating in designs, such as F553, that withstood unfolding forces exceeding 1,000 pN. This represents a more than fourfold increase over the benchmark titin I27 domain, measured under identical experimental conditions. This nanonewton-scale stability is rooted in the same shear-based mechanism employed by some of nature's most resilient non-covalent interactions, such as the extreme mechanostable bacterial adhesin complex SdrG-Fg β . Furthermore, our proteins maintained their native fold after being subjected to 150 °C, highlighting their extreme robustness. These findings show how computational design can push the stability of synthetic proteins to levels that rival many natural systems, offering a scalable strategy for creating proteins designed for extreme environments.

An outcome of our work is the successful translation of these molecular-level enhancements into robust macroscopic materials. By incorporating the SuperMyo proteins as physical cross-linkers, we created hydrogels that remained structurally intact after autoclaving, a standard sterilization process that typically denatures and dissolves most protein-based biomaterials. This excellent thermal stability stands in contrast to many other engineered protein hydrogels, which often have lower denaturation temperatures, limiting their processing and application range. Our results provide powerful evidence that engineering extreme stability at the single-molecule level can directly yield materials with properties suitable for applications requiring both biocompatibility and resilience to harsh processing conditions.

The primary innovation enabling these results is our high-throughput computational pipeline. The integration of state-of-art generative AI design tools (RFdiffusion, ProteinMPNN, AF2/ESM-Fold) with MD simulations for prescreening allowed us to efficiently navigate a vast design space and rationally test the hydrogen-bond maximization principle on an unprecedented scale. This approach

Fig. 5 | SuperMyo constructed as protein hydrogels demonstrating superior macroscopic properties. **a**, SuperMyo proteins A339 and B42, like natural I27, were successfully assembled into hydrogels using the classic SpyTag–SpyCatcher reaction system. **b**, Rheology experiments confirmed the formation of stable

protein hydrogels. **c**, At high temperatures, hydrogels derived from A339 and B42 remained transparent, whereas the natural I27-based hydrogel turned opaque, indicating loss of structural integrity. **d**, Real-time temperature-dependent rheology measurements.

provides a generalizable framework for engineering proteins with high-performance properties. By streamlining the design–test–learn cycle, our methodology makes the creation of superstable proteins more systematic and accessible. Beyond stability, this integrated approach could be extended to co-optimize proteins for both structure and function, aiding in the rational design of biomaterials and therapeutics with tailored properties.

In conclusion, by applying fundamental chemical principles through the AI + MD computational framework, we have designed, validated and utilized a new class of synthetic proteins with outstanding stabilities. Moving forward, a key objective is to use these proteins as core components for advanced materials, exploring their potential in areas ranging from durable hydrogels to resilient coatings for extreme environments. Our findings not only provide quantitative insights into the molecular determinants of mechanostability but also establish a clear blueprint for engineering resilient protein-based materials from the molecule up, opening possibilities for biotechnology in extreme environments.

Methods

Protein expression and purification

All designed SuperMyo genes were ordered from General Biol. Each protein was constructed into the pET30a vector using the BamHI–KpnI restriction enzyme system, resulting in constructs such as pET30a-GGG-POI-his8-strep-NAL for thermal cycling experiments, pET30a-SdrG-GB1-POI-GB1-his6-NAL for unfolding and refolding force spectroscopy experiments and pQE80L-spytag-POI-spytag-POI-spytag-his6 for hydrogel construction. The plasmids were transformed into BL21(DE3) cells. Single colonies were selected and cultured overnight at 37 °C in LB medium containing kanamycin for pET30a vector or ampicillin for pQE80L vector. The culture was then transferred to 800 ml of kanamycin-containing LB and incubated for 2 h at 37 °C on a shaker. When the OD₆₀₀ of the culture reached 0.6–0.8, isopropyl-β-D-1-thiogalactopyranoside (IPTG) was added to a final concentration of 0.5 mM, and the culture was incubated at 18 °C on the shaker for 16 h.

The bacteria were harvested by centrifugation at 13,000g for 10 min at 12 °C, and resuspended by the lysis buffer containing 20 mM Tris–HCl, 150 mM NaCl, pH 7.4. Prior to cell lysis, DNase, RNase and PMSF were added to the cell suspension. The suspension was then lysed using a homogenizer for 3 min, followed by centrifugation at 39,000g for 15 min at 6 °C to separate the supernatant fraction.

Proteins SdrG-GB1-POI-GB1-his6-NAL and spytag-POI-spytag-POI-spytag-his6 were purified using a Ni-NTA affinity chromatography column. Impurities were washed with a wash buffer (20 mM Tris–HCl, 400 mM NaCl, 20 mM imidazole, pH 7.4) and bound proteins were eluted by an elution buffer (20 mM Tris–HCl, 150 mM NaCl, 250 mM imidazole, pH 7.4). Protein concentrations were quantified by measuring the absorbance at 280 nm.

GGG-POI-his8-strep-NAL was purified by STarm Sreptactin, and impurities were washed away using a wash buffer (20 mM Tris, 1 M NaCl, pH 7.4, 2 mM EDTA, 1 mM dithiothreitol). GGG-POI-his8-strep-NAL was then eluted using an elution buffer (20 mM Tris, 150 mM NaCl, 10 mM biotin, pH 7.4).

OaAEP1(C247A) is cysteine 247 to the alanine mutant of asparaginyl endoproteases 1 from *Oldenlandia affinis*, abbreviated as OaAEP1 here⁷⁴. ELP is the elastin-like polypeptides⁵⁷.

RFdiffusion design of SuperMyo protein

Because the simultaneous rupture of main-chain hydrogen bonds in force-bearing β strands is a major contributor to protein unfolding forces, we aimed to design mechanically stronger proteins by elongating these β strands using the RFdiffusion model. This elongation resulted in an increase in the number of corresponding main-chain hydrogen bonds. Experimental results showed that, as a diffusion model, RFdiffusion exhibits inherent stochasticity during sampling, making it challenging to achieve substantial β-strand lengthening in a single step. To overcome this limitation, we focused on the force-bearing β strands of I27 and iteratively elongated their length, effectively guiding the β strands to evolve towards the desired structural features. Over six iterations (series A, B, C, D, E and F), the number of main-chain hydrogen bonds was increased from 4 to 33, with each series corresponding to 8, 13, 18, 23, 28 and 33 hydrogen bonds, respectively.

Taking the A series of designs as an example, we used I27 (PDB 1TIT) as the initial structure and performed motif scaffolding on residues 10–14 and 83–88 by setting the input contigmap.contigs = [1-2/A10-14/60-100/A83-87/1-2], generating a total of 1,000 backbone structures. The generated structures were screened based on two criteria: (1) eliminating physically unrealistic structures, such as those with atomic overlaps or chain entanglements; (2) conducting secondary structure analysis to retain only those structures where the N- and C-terminal β strands (force-bearing regions) were longer than those in the initial input. This approach successfully achieved β-strand elongation.

Sequence design and structure prediction

Because RFdiffusion only generates protein backbones, it is necessary to use ProteinMPNN to design amino acid sequences that can fold into the corresponding structures. For each generated backbone, 400 sequences were sampled with the temperature parameter set to 0.1. Cysteine residues were excluded during the generation to avoid the formation of intramolecular or intermolecular disulfide bonds. Before structural prediction, all sequences underwent a preliminary hydrophobicity assessment. To compensate for the loss, additional sequences were generated using ProteinMPNN to supplement the dataset. Specifically, each of the 20 natural amino acids was assigned a hydrophobicity score, and the overall hydrophobicity of a protein was calculated as the average hydrophobicity score of its constituent residues. This step aimed to mitigate potential challenges in protein expression caused by excessive hydrophobicity.

The screened sequences were then subjected to structure prediction using ESMFold. The predicted structures were evaluated by calculating the pLDDT scores and comparing them with the original RFdiffusion-generated backbones to determine the C_α r.m.s.d. values. Only structures with pLDDT scores >90 and r.m.s.d. values <0.2 nm were retained.

The structures that passed the ESMFold screening were then ranked by their pLDDT scores, and the top 1,000 structures were further predicted using AlphaFold2 (five models with 12 recycles). The same pLDDT and RMSD criteria were applied, and the final 200 top-ranked structures based on pLDDT were selected for downstream MD simulation screening.

Using this iterative approach, we designed six SuperMyo proteins with progressively extended force-bearing β chains, designated as series A, B, C, D, E and F. The sequences and structures generated by the AI models were labelled using the format SeriesName-StructureIndex-SequenceIndex. For example, 'A339' is an abbreviation for 'A_243_339'. The full names of these proteins are described in Supplementary Data 2.

SMD simulation for SuperMyo unfolding

To identify proteins with high unfolding forces, we conducted SMD simulations on target proteins predicted by AlphaFold2, using the GROMACS 2023.3 software package³⁷. Protein structure files were preprocessed with the Biopython package to align the N terminus and C terminus along the z axis, the designated pulling direction. The size of the simulation water box was determined based on the protein size and the pulling distance. Specifically, the x and y boundaries of the simulation box were set to 1.2 nm from the protein surface, while the z-axis length was calculated as the sum of the pulling distance and the folded protein's length along the z axis. The pulling distance for each protein varied and was set to one-quarter of the contour length (pulling distance = $\Delta L_c \times 0.25$). The systems were then solvated and neutralized using 150 mM NaCl. All simulation systems utilized the CHARMM36m force field⁴¹ and the TIP3P water model.

Prior to the SMD simulations, each system underwent 5,000 steps of energy minimization to eliminate steric clashes and optimize the initial configuration. This was followed by 125 ps of NVT simulations with positional restraints on the protein backbone atoms. A subsequent 10-ns pre-equilibration in the NPT ensemble was conducted under periodic boundary conditions, maintaining a temperature of 310 K using the V-rescale thermostat and a pressure of 1 bar using the C-rescale barostat.

For the SMD simulations (repeated three times per protein), the C terminus of the protein was restrained with a fixed harmonic potential (1,000 kJ mol^{−1} nm^{−2} for the x, y, z direction), while a harmonic pulling potential (1,000 kJ mol^{−1} nm^{−2}) was applied along the positive z axis to the C_α atoms of the N-terminal residues to induce unfolding with a constant pulling speed (1 nm ns^{−1} or 0.1 nm ns^{−1}). The simulation time required for the pulling was determined by the pulling length and

pulling speed, and was calculated as follows: time = pulling length (nm)/pulling speed (nm ns^{-1}). The force–distance curves generated from the SMD simulations provided the unfolding forces of the proteins. The mechanical strength of the protein was evaluated by averaging the unfolding forces obtained from the three simulations.

The force-bearing β -strand backbone hydrogen-bond analysis was performed on the SMD trajectories using the *gmx hbond* utility from the GROMACS package, focusing specifically on the backbone atoms of these strands. A hydrogen bond was defined by the default geometric criteria (donor–acceptor distance, <0.35 nm; hydrogen donor–acceptor angle, $<30^\circ$). The number of hydrogen bonds was then plotted against simulation time using Python's Matplotlib library.

Annealing MD simulation of SuperMyo

To screen for SuperMyo with better thermal stability, we conducted annealing simulations on the designed proteins. The simulations were performed using the GROMACS 2023.3 software package with the CHARMM36m force field and the TIP3P water model. The size of the cubic simulation box was determined by adding 2.4 nm to the longest axis of the protein to ensure adequate solvation. Prior to the annealing simulations, the systems underwent 5,000 steps of energy minimization and 1 ns of position-restrained MD simulations.

During the annealing simulations, the solvent (water and ions) and the protein solute were temperature controlled as two separate groups. In the 1,000-ns simulations, the temperature was linearly increased from 0 K to 310 K over the first 10 ns and then further linearly increased to 413 K for the remainder of the simulation. The execution of the MD simulations was automatically managed by a Python script.

AFM–SMFS unfolding experiment

An AFM cantilever/tip made of silicon nitride (MLCT-BIO-DC, Bruker) was used. The detailed protocol for AFM tip functionalization and protein immobilization on the glass coverslip can be found in ref. 56. In short, the tip and glass coverslip were coated with the amino group by amino-silanization. The N_3 - group is functionalized on the surface from the reaction between $\text{ImSO}_2\text{N}_3\text{-HCl}$ and $-\text{NH}_2$. Then, a heterobifunctional DBCO-PEGn-Mal can be reacted and adds the Mal group. Next, the peptide GL-(ELP)₂₀-C was reacted to the maleimide via the cysteine, respectively. The long (ELP)₂₀ serves as a spacer to avoid non-specific interaction between the tip and the surface and provides a signature for the single-molecule event. Finally, target protein SuperMyo with C-terminal NAL sequence or Fg β -GB1-NAL sequence can be site-specifically linked to the coverslip or tip by OaAEP1, respectively.

An atomic force microscope (Nanowizard4, JPK) was used to acquire the force–extension curves. The D tip of the MLCT-Bio-DC cantilever was used. Its accurate spring constant was determined by a thermally induced fluctuation method⁷⁵. Typically, the tip contacted the protein-immobilized surface for 50 ms under an indentation force of 350 pN to ensure a site-specific interaction. Then, moving the tip up vertically at a constant velocity ($1 \mu\text{m s}^{-1}$), the polyprotein unfolded. Then, the tip moved to another place to repeat this cycle several thousands of times. This yielded a force–extension curve, which was analysed using JPK data-processing analysis software.

AFM–SMFS refolding experiment

To evaluate the refolding capability of SuperMyo, protein unfolding experiments were performed using the SMFS method as previously described. When the *v*Deflection detected by the tip reached 1 nN (less than the dissociation force of the SdrG–Fg β complex, indicating that the complex had not dissociated), the tip immediately approached the substrate, and the unfolded SuperMyo protein was quickly relaxed to zero extension length (with the distance between the tip and the substrate being ~ 5 nm). At this point, SuperMyo remained attached to the tip. After a 400-ms pause, the tip was retracted again to induce the

unfolding of SuperMyo. This process was repeated hundreds of times until the SdrG–Fg β complex dissociated, and SuperMyo was no longer picked up by the AFM tip, after which the next cycle started.

NMR sample preparation

^{15}N -labelled samples were prepared by supplementing the minimal (M9) medium with $^{15}\text{NH}_4\text{Cl}$ (1 g l^{-1}). $^{15}\text{N}/^{13}\text{C}$ -labelled samples were prepared by supplementing the minimal (M9) medium with $^{15}\text{NH}_4\text{Cl}$ (1 g l^{-1}) and $^{13}\text{C}_6$ -glucose (2 g l^{-1}). BL21 was grown in M9 medium at 37°C to an absorbance at 600 nm of ~ 0.6 . Protein induction was induced by the addition of 0.2 mM IPTG and cells were allowed to grow for 16 h at 18°C . Cells were harvested and resuspended in lysis buffer (50 mM sodium phosphate, 500 mM NaCl, pH 8.0). Cells were disrupted by sonication. Proteins were purified using Ni Sepharose 6 Fast Flow resin, followed by gel filtration using a Superdex 75 16/600 column.

NMR structure calculation

For resonance assignment, ^{15}N , ^{13}C -labelled A339 protein sample at a concentration of 800 μM was prepared in 93% $\text{H}_2\text{O}/7\%$ D_2O solution of 20 mM KPi (pH 7.0), 75 mM KCl, 0.05% NaN_3 and 1% Halt Protease Inhibitor Cocktail (Thermo Scientific). All NMR experiments were recorded on Bruker AVANCE 600-MHz devices equipped with 5-mm cryogenic probes. All NMR spectra were recorded at 25°C . The spectra were processed with NMRPipe⁷⁶ and analysed using NMRFAM Sparky⁷⁷. Backbone and side-chain resonances were assigned manually with the help of PINE⁷⁸. $^1\text{H}^\text{N}$, H^β , H^α , ^{15}N , $^{13}\text{C}^\alpha$, $^{13}\text{C}^\beta$ and C' backbone resonance assignments were obtained from HNCACB, CBCA(CO)NH, CCONH, HBHACONH, HCCCONH, HNCO, HN(CA)CO and CCHTOCSY.

NMR structures of A339 protein were generated using nuclear Overhauser effect (NOE) peak lists from three-dimensional ^{13}C -edited nuclear overhauser effect spectroscopy–heteronuclear single quantum coherence (NOESY–HSQC), and ^{15}N -edited NOESY–HSQC from ^{13}C , ^{15}N -labelled samples. The $^{13}\text{C}^\alpha$, $^{13}\text{C}^\beta$, $^{13}\text{C}'$, ^{15}N and $^1\text{H}^\text{N}$ chemical shifts served as input for the TALOS-N program⁷⁹ to extract dihedral angles (φ and ψ). A large number of intramolecular NOEs were collected to determine the hydrogen bonds. The structures were calculated with CYANA 3.98 (ref. 80). Structure statistics were extracted from the PSVS⁸¹.

CD experiments

For CD experiments, SuperMyo were diluted to 0.1 mg ml^{-1} in 10 mM KPO_4 (pH 7.4) buffer. Spectra were acquired on a Chirascan V100 (Applied Photophysics). The temperature of the sample was ramped from 25°C to 92°C with full spectrum scans from 190 nm to 260 nm performed after each 5°C interval. All reported measurements were acquired within the linear range of the instrument.

Heating cycles and 150°C heating experiments

To verify the stability and functionality of SuperMyo under extreme temperature conditions, we subjected A339, B42 and A352 to 10 cycles of heat treatment ranging from 121°C to -196°C . The proteins used in this experiment differ from those in previous SMFS studies. Because SdrG loses its binding ability to Fg β after heating, we constructed the GGG-SuperMyo-NAL protein for heating experiments to avoid interfering with the results.

In each test, a 1.5-ml centrifuge tube containing 1 ml of a $1\text{--}2 \text{ mg ml}^{-1}$ protein solution (with sterilization indicator tape on the outer wall) was placed into a polytetrafluoroethylene (PTFE)-lined high-pressure reactor. Thermally sensitive paper (Thermax) was placed with the solution into the reactor. The reactor was heated in an oven at 121°C or 150°C for 1 h. After cooling to room temperature, a colour change in the sterilization indicator tape was observed, accompanied by a colour shift in the thermally sensitive paper at the specified temperature. For the 121°C heating test, the tube was then immersed in liquid nitrogen until the protein solution was completely frozen. This heating and cooling cycle was repeated 10 times.

After the heating–cooling cycles, 40 μl of GGG-SuperMyo-NAL was mixed with 10 μl of OaAEP1 and applied to the substrate modified with GL-(ELP)₂₀. The reaction was carried out at 25 °C for 1 h. The substrate was then washed three times with ultrapure water and 1 M NaCl solution, respectively. Next, 40 μl of SdrG-(GB1)₂-LPETGG was mixed with 10 μl of MgSrtA, and CaCl₂ was added to a final concentration of 5 mM. This mixture was then dropped on to the substrate and allowed to react at 25 °C for 1 h. The substrate was subsequently washed three times with ultrapure water and 1 M NaCl solution, respectively. After this, the SMFS experiment was conducted as previously described.

Hydrogel construction and rheology measurements

First, 60 μl of four-arm PEG-Spycatcher (120 mg ml⁻¹ lyophilized powder dissolved in PBS buffer, pH 7.2) was mixed with 40 μl of Spytag-127-Spytag-127-Spytag (100 mg ml⁻¹ in PBS), or 40 μl of Spytag-339-Spytag-339-Spytag (119 mg ml⁻¹ in PBS), or 40 μl of Spytag-42-Spytag-42-Spytag (113 mg ml⁻¹ in PBS). The mixture was vortexed and then centrifuged at 8,000 r.p.m. for 30 s. Following centrifugation, the solution was transferred to a tube or measurement plate, and left to stand at room temperature for 5 min to form the gel.

Rheology was performed on a TA DHR-2 Rheometer, with an 8-mm standard flat steel parallel plate. The edge of the gel was surrounded with silicone oil to minimize evaporation. Strain sweep experiments were performed at 10 rad s⁻¹ from 0.1% to 100% strain amplitude at 25 °C. Temperature sweeps were run from 25 °C to 95 °C at a rate of 5 °C min⁻¹ and a frequency of 10 rad s⁻¹ at a strain of 2%.

Data availability

All data are available in the main text or in the Supplementary Information. The AlphaFold2-predicted structure of the designed SuperMyo protein is provided in Supplementary Data 1, and the screening metric data generated during the design process are available in Supplementary Data 2. The solution NMR structure for A339 in Fig. 2g has been deposited in the PDB (9UKW). Source data are provided with this paper.

Code availability

The Python script for automated execution of annealing simulations and SMD is available via GitHub at <https://github.com/Andachten/AutoMD>.

Materials and Methods

Protein Expression and Purification.

All designed SuperMyo genes were ordered from General Biol. Each protein was constructed into the pET30a vector using the *Bam*HI-*Kpn*I restriction enzyme system, resulting in constructs such as pET30a-GGG-POI-his8-strep-NAL for thermal cycling experiments, pET30a-sdrG-GB1-POI-GB1-his6-NAL for unfolding and refolding force spectroscopy experiments and pQE80L-spytag-POI-spytag-POI-spytag-his6 for hydrogel construction. The plasmids were transformed into BL21(DE3) cells. Single colonies were selected and cultured overnight at 37°C in LB medium containing kanamycin for pET30a vector or Ampicillin for pQE80L vector. The culture was then transferred to 800 mL of kanamycin-containing LB and incubated for 2 hours at 37°C on a shaker. When the OD₆₀₀ of the culture reached 0.6-0.8, isopropyl-β-D-1-thiogalactopyranoside (IPTG) was added to a final concentration of 0.5 mM, and the culture was incubated at 18°C on the shaker for 16 hours.

The bacteria were harvested by centrifugation at 13,000 × g for 10 min at 12 °C, and resuspended by the lysis buffer containing 20 mM Tris-HCl, 150 mM NaCl, pH 7.4. Prior to cell lysis, DNase, RNase, and PMSF were added to the cell suspension. The suspension was then lysed using a homogenizer for 3 minutes, followed by centrifugation at 39,000 × g for 15 minutes at 6°C to separate the supernatant fraction.

Proteins sdrG-GB1-POI-GB1-his6-NAL and spytag-POI-spytag-POI-spytag-his6 were purified by Ni-NTA affinity chromatography column. Impurities were washed with a Wash buffer (20 mM Tris-HCl, 400 mM NaCl, 20 mM imidazole, pH 7.4) and bound proteins was eluted by Elution buffer (20 mM Tris-HCl, 150 mM NaCl, 250 mM imidazole, pH 7.4). Protein concentrations were quantified by measuring the absorbance at 280 nm.

GGG-POI-his8-strep-NAL was purified by STarm Sreptactin, and impurities were washed away using Wash buffer (20 mM Tris, 1M NaCl, pH 7.4, 2 mM EDTA, 1 mM DTT). GGG-POI-his8-strep-NAL was then eluted using Elution buffer (20 mM Tris, 150 mM NaCl, 10 mM biotin, pH 7.4).

*Oa*AEPI(C247A) is cysteine 247 to alanine mutant of asparaginyl endoproteases 1 from *oldenlandia affinis*, abbreviated as *Oa*AEPI here¹. ELP is the elastin-like polypeptides².

RFdiffusion Design of SuperMyo Protein

Considering that the simultaneous rupture of main-chain hydrogen bonds in force-bearing β-strands is a significant contributor to protein unfolding forces, we aimed to design mechanically stronger proteins by elongating these β-strands using the RFdiffusion model. This elongation resulted in an increase in the number of corresponding main-chain hydrogen bonds. Experimental results showed that, as a diffusion model, RFdiffusion exhibits inherent stochasticity during sampling, making it challenging to achieve substantial β-strand lengthening in a single step. To overcome this limitation, we focused on the force-bearing β-strands of I27 and iteratively elongated their length, effectively guiding the β-strands to evolve towards the desired structural features. Over six iterations (series A, B, C, D, E and F), the

number of main-chain hydrogen bonds was increased from 4 to 33, with each series corresponding to 8, 13, 18, 23, 28, and 33 hydrogen bonds, respectively.

Taking the A-series of designs as an example, we used I27 (PDB code: 1TIT) as the initial structure and performed motif scaffolding on residues 10-14 and 83-88 by setting the input `contigmap.contigs=[1-2/A10-14/60-100/A83-87/1-2]`, generating a total of 1000 backbone structures. The generated structures were screened based on two criteria: (1) eliminating physically unrealistic structures, such as those with atomic overlaps or chain entanglements; (2) conducting secondary structure analysis to retain only those structures where the N- and C-terminal β -strands (force-bearing regions) were longer than those in the initial input. This approach successfully achieved β -strand elongation.

Sequence Design and Structure Prediction

Since RFdiffusion only generates protein backbones, it is necessary to use ProteinMPNN to design amino acid sequences that can fold into the corresponding structures. For each generated backbone, 400 sequences were sampled with the temperature parameter set to 0.1. Cysteine residues were excluded during the generation to avoid the formation of intramolecular or intermolecular disulfide bonds. Before structural prediction, all sequences underwent a preliminary hydrophobicity assessment. To compensate for the loss, additional sequences will be generated using ProteinMPNN to supplement the dataset. Specifically, each of the 20 natural amino acids was assigned a hydrophobicity score, and the overall hydrophobicity of a protein was calculated as the average hydrophobicity score of its constituent residues. This step aimed to mitigate potential challenges in protein expression caused by excessive hydrophobicity.

The screened sequences were then subjected to structure prediction using ESMFold. The predicted structures were evaluated by calculating the pLDDT scores and comparing them with the original RFdiffusion-generated backbones to determine the C α RMSD values. Only structures with pLDDT scores above 90 and RMSD values below 0.2 nm were retained.

The structures that passed the ESMFold screening were then ranked by their pLDDT scores, and the top 1000 structures were further predicted using AlphaFold2 (five models with 12 recycles). The same pLDDT and RMSD criteria were applied, and the final 200 top-ranked structures based on pLDDT were selected for downstream MD simulation screening.

Using this iterative approach, we designed six SuperMyo proteins with progressively extended force-bearing β -chains, designated as series A, B, C, D, E, and F. The sequences and structures generated by the AI models were labeled using the format "SeriesName-StructureIndex-SequenceIndex." For example, 'A339' is an abbreviation for 'A_243_339.' The full names of these proteins are described in Data S2.

SMD Simulation for SuperMyo Unfolding.

To identify proteins with high unfolding forces, we conducted SMD simulations on target proteins predicted by AlphaFold2, using the GROMACS 2023.3 software package³. Protein structure files were pre-processed with the Biopython package to align the N-terminus and C-terminus along the z-axis, the designated pulling direction. The size of the simulation water box was determined based on the protein size and the pulling distance. Specifically, the x and y boundaries of the simulation box were set to 1.2 nm from the protein surface, while the z-axis length was calculated as the sum of the pulling distance and the folded protein's length along the z-axis. The pulling distance for each protein varied and was set to one-fourth of the contour length (pulling distance = $\Delta L_c * 0.25$). The systems were then solvated and neutralized using 150 mM NaCl. All simulation systems utilized the CHARMM36m force field⁴ and the TIP3P water model.

Prior to the SMD simulations, each system underwent 5000 steps of energy minimization to eliminate steric clashes and optimize the initial configuration. This was followed by 125 ps of NVT simulations with positional restraints on the protein backbone atoms. A subsequent 10 ns pre-equilibration in the NpT ensemble was conducted under periodic boundary conditions, maintaining a temperature of 310 K using the V-rescale thermostat and a pressure of 1 bar using the C-rescale barostat.

For the SMD simulations (repeated three times per protein), the C-terminal of the protein was restrained with a fixed harmonic potential (1000 kJ/mol/nm² for x, y, z direction), while a harmonic pulling potential (1000 kJ/mol/nm²) was applied along the positive z-axis to the C α atoms of the N-terminal residues to induce unfolding with a constant pulling speed (1 nm/ns or 0.1 nm/ns). The simulation time required for the pulling was determined by the pulling length and pulling speed, and was calculated as follows: time = pulling length (nm) / pulling speed (nm/ns). The force-distance curves generated from the SMD simulations provided the unfolding forces of the proteins. The mechanical strength of the protein was evaluated by averaging the unfolding forces obtained from the three simulations.

The force-bearing β -stands backbone hydrogen bonds analysis was performed on the SMD trajectories using the “gmhbond” utility from the GROMACS package, focusing specifically on the backbone atoms of these strands. A hydrogen bond was defined by the default geometric criteria (donor-acceptor distance less than 0.35 nm; hydrogen-donor-acceptor angle less than 30°). The number of hydrogen bonds was then plotted against simulation time using Python's Matplotlib library.

Annealing MD Simulation of SuperMyo

To screen for SuperMyo with better thermal stability, we conducted annealing simulations on the designed proteins. The simulations were performed using the GROMACS 2023.3 software package with the CHARMM36m force field and the TIP3P water model. The size of the cubic simulation box was determined by adding 2.4 nm to the longest axis of the protein to ensure adequate solvation. Prior to the annealing simulations, the systems underwent 5000 steps of energy minimization and 1 ns of position-restrained MD simulations.

During the annealing simulations, the solvent (water and ions) and the protein solute were temperature-controlled as two separate groups. In the 1000 ns simulations, the temperature was linearly increased from 0 K to 310 K over the first 10 ns and then further linearly increased to 413 K for the remainder of the simulation. The execution of the MD simulations was automatically managed by a Python script.

AFM-SMFS Unfolding Experiment.

The AFM cantilever/tip made of silicon nitride (MLCT-BIO-DC, Bruker Corp.) was used. The detailed protocol for AFM tip functionalization and protein immobilization on the glass coverslip can be found in reference⁵. In short, the tip and glass coverslip were coated with the amino group by amino-silanization. N₃- group is functionalized on the surface from the reaction between ImSO₂N₃·HCl and -NH₂. Then, a heterobifunctional DBCO-PEGn-Mal can be reacted and adds the Mal group. Next, the peptide GL-(ELP)₂₀-C was reacted to the maleimide via the cysteine, respectively. The long (ELP)₂₀ serves as a spacer to avoid non-specific interaction between the tip and the surface as well as a signature for the single-molecule event. Finally, target protein SuperMyo with C-terminal NAL sequence or Fgβ-GB1-NAL sequence can be site-specifically linked to the coverslip or tip by *Oa*AEPI, respectively.

Atomic force microscope (Nanowizard4, JPK) was used to acquire the force-extension curves. The D tip of the MLCT-Bio-DC cantilever was used. Its accurate spring constant was determined by a thermally-induced fluctuation method⁶. Typically, the tip contacted the protein-immobilized surface for 50 ms under an indentation force of 350 pN to ensure a site-specifically interaction. Then, moving the tip up vertically at a constant velocity (1 μm/s), the polyprotein unfolded. Then, the tip moved to another place to repeat this cycle several thousands of times. As a result, the force-extension curve was obtained, which was analyzed using JPK data process analysis software.

AFM-SMFS Refolding Experiment.

To evaluate the refolding capability of SuperMyo, protein unfolding experiments were performed using the SMFS method as previously described. When the vDeflection detected by the tip reached 1nN (less than the dissociation force of the sdrG-Fgβ complex, indicating that the complex had not dissociated), the tip immediately approaches to the substrate, and the unfolded SuperMyo protein was quickly relaxed to zero extension length (with the distance between the tip and the substrate being approximately 5nm). At this point, SuperMyo remained attached to the tip. After a 400 ms pause, the tip was retracted again to induce the unfolding of SuperMyo. This process was repeated hundreds of times until the sdrG-Fgβ complex dissociated, and SuperMyo was no longer picked up by the AFM tip, after which the next cycle started.

NMR Sample Preparation

^{15}N -labelled samples were prepared by supplementing the minimal (M9) medium with $^{15}\text{NH}_4\text{Cl}$ (1 g L^{-1}). $^{15}\text{N}/^{13}\text{C}$ -labelled samples were prepared by supplementing the minimal (M9) medium with $^{15}\text{NH}_4\text{Cl}$ (1 g L^{-1}) and $^{13}\text{C6}$ -glucose (2 g L^{-1}). BL21 grown in M9 medium at $37\text{ }^\circ\text{C}$ to an absorbance at 600 nm ($A_{600\text{ nm}}$) ≈ 0.6 . Protein induction was induced by the addition of 0.2 mM IPTG and cells were allowed to grow for 16 h at $18\text{ }^\circ\text{C}$. Cells were harvested and resuspended in lysis buffer (50 mM sodium phosphate, 500 mM NaCl, $\text{pH } 8.0$). Cells were disrupted by sonication. Proteins were purified using Ni Sepharose 6 Fast Flow resin, followed by gel filtration using Superdex 75 $16/600$ column.

NMR Structure Calculation

For resonance assignment, ^{15}N , ^{13}C -labeled A339 protein sample at concentration of $800\mu\text{M}$ is prepared in 93% $\text{H}_2\text{O}/7\%$ D_2O solution of 20 mM KPi ($\text{pH } 7.0$), 75 mM KCl, 0.05% NaN_3 and 1% Halt Protease Inhibitor Cocktail (Thermo Scientific). All NMR experiments were recorded on Bruker AVANCE 600-MHz devices equipped with 5-mm cryogenic probes. All NMR spectra were recorded at $25\text{ }^\circ\text{C}$. The spectra were processed with NMRPipe⁷ and analyzed using NMRFAM Sparky⁸. Backbone and side-chain resonances were assigned manually with the help of PINE⁹. $^1\text{H}^{\text{N}}$, H^{β} , H^{α} , ^{15}N , $^{13}\text{C}^{\alpha}$, $^{13}\text{C}^{\beta}$, and C' backbone resonance assignments were obtained from HNCACB, CBCA(CO)NH, CCCONH, HBHACONH, HCCCONH, HNCO, HN(CA)CO and CCHTOCSY.

NMR structures of A339 protein were generated using NOE peak lists from 3D ^{13}C -edited NOESY-HSQC, and ^{15}N -edited NOESY-HSQC from ^{13}C , ^{15}N -labelled samples. The $^{13}\text{C}^{\alpha}$, $^{13}\text{C}^{\beta}$, $^{13}\text{C}'$, ^{15}N and $^1\text{H}^{\text{N}}$ chemical shifts served as input for the TALOS-N program¹⁰ to extract dihedral angles (ϕ and ψ). A large number of intramolecular NOEs were collected for determining hydrogen bond. The structures were calculated with CYANA 3.98 ¹¹. Structure statistics were extracted from the PSVS¹².

Circular Dichroism Experiments

For circular dichroism (CD) experiments, SuperMyo were diluted to 0.1 mg/mL in 10 mM K- PO_4 ($\text{pH } 7.4$) buffer. Spectra were acquired on a Chirascan V100 (Applied Photophysics). The temperature of the sample was ramped from $25\text{ }^\circ\text{C}$ to $92\text{ }^\circ\text{C}$ with full spectrum scans from 190 nm to 260 nm performed after each $5\text{ }^\circ\text{C}$ interval. All reported measurements were acquired within the linear range of the instrument.

Heating Cycles and $150\text{ }^\circ\text{C}$ Heating Experiments

To verify the stability and functionality of SuperMyo under extreme temperature conditions, we subjected A339, B42, and A352 to 10 cycles of heat treatment ranging from $121\text{ }^\circ\text{C}$ to $-196\text{ }^\circ\text{C}$. The proteins used in this experiment differ from those in previous SMFS studies. Since sdrG loses its binding ability to $\text{Fg}\beta$ after heating, we

constructed the GGG-SuperMyo-NAL protein for heating experiments to avoid interfering with the results.

In each test, a 1.5 mL centrifuge tube containing 1 mL of a 1-2 mg/mL protein solution (with sterilization indicator tape on the outer wall) was placed into a polytetrafluoroethylene (PTFE) lined high-pressure reactor. The thermal-sensitive paper (thermax) was placed together into the reactor liner. The reactor was heated in an oven at 121°C or 150°C for 1 hour. After cooling to room temperature, a color change in the sterilization indicator tape was observed, accompanied by a color shift in the thermal-sensitive paper at the specified temperature. For 121°C heating test, the tube was then immersed in liquid nitrogen until the protein solution was completely frozen. This heating and cooling cycle was repeated ten times.

After the heating-cooling cycles, 40 μ L of GGG-SuperMyo-NAL was mixed with 10 μ L of *Oa*AEPI and applied to the substrate modified with GL-(ELP)₂₀. The reaction was carried out at 25°C for 1 hour. The substrate was then washed three times with ultrapure water and 1 M NaCl solution, respectively. Next, 40 μ L of sdrG-(GB1)₂-LPETGG was mixed with 10 μ L of mgSrtA, and CaCl₂ was added to a final concentration of 5 mM. This mixture was then dropped to the substrate and allowed to react at 25°C for 1 hour. The substrate was subsequently washed three times with ultrapure water and 1 M NaCl solution, respectively. After this, the SMFS experiment was conducted as previously described.

Hydrogel Construction and Rheology Measurements

60 μ L of 4-arm PEG-Spycatcher (120 mg/mL lyophilized powder dissolved in PBS buffer, pH 7.2) is mixed with 40 μ L of Spytag-I27-Spytag-I27-Spytag (100 mg/mL in PBS), or 40 μ L of Spytag-339-Spytag-339-Spytag (119 mg/mL in PBS), or 40 μ L of Spytag-42-Spytag-42-Spytag (113 mg/mL in PBS). The mixture is vortexed and then centrifuged at 8000 rpm for 30 seconds. Following centrifugation, the solution is transferred to a tube or measurement plate, where it is left to stand at room temperature for 5 minutes to form the gel.

Rheology was performed on a TA DHR-2 Rheometer, with an 8 mm standard flat steel parallel plate. The edge of the gel was surrounded with silicone oil to minimize evaporation. Strain sweep experiments were performed at 10 rad/s from 0.1-100 % strain amplitude at 25 °C. Temperature sweeps were run from 25-95 °C at a rate of 5 °C min⁻¹ and a frequency of 10 rad/s at strain of 2%.

Fig. 1.

Fig. 1 Schematic of the SuperMyo protein design. a, Flowchart of the SuperMyo Design Process: Starting with the extraction of force-bearing β -strands from an initial structure, novel protein designs are generated using RFdiffusion, ProteinMPNN, and deep learning-based structure prediction tools. Mechanical and thermodynamic properties are then screened using SMD and annealing simulations. **b**, Topologies of the I27 and SuperMyo A-series proteins (A25, A218 and A339). Arrows denote β -strands and cylinders denote α -helices. Force-bearing β -strands are colored yellow, and backbone hydrogen bonds are shown as blue lines. The initial design significantly extended the force-bearing β -strands relative to the titin I27 template.

Fig. 2.

Fig. 2 Protein Immobilization in AFM-SMFS Experiments. **a**, Peptide GL-(ELP)₂₀-Cys is modified on a glass substrate (or AFM tip) that has been functionalized with maleimide through Michael addition reaction. **b**, The N-terminus GL can undergo an enzymatic ligation reaction with the C-terminus NAL of the target protein in the presence of *OaAEP1*, thereby immobilizing the target protein on the substrate or AFM tip. **c**, To avoid the influence of fusion proteins (sdrG and GB1) on the heating cycle tests, the GGG-SuperMyo-NAL protein is subjected to heating cycles alone. Afterward, the N-terminal NAL is ligated to the GL tag on the substrate using *OaAEP1*. Subsequently, the molecular handle and the fingerprint protein sdrG-(GB1)₂ with the C-terminal LPETGG are ligated to the N-terminal GGG of SuperMyo through mgSrtA.

Fig. 3.

Fig. 3 AlphaFold2 Structure Prediction Results. The structure predictions of SuperMyo A339, B42, C352, D399, E389 and F553, respectively, as predicted by AlphaFold2. Blue indicates high confidence in the predicted results.

Fig. 4.

Fig. 4 Unfolding snapshot of SuperMyo in SMD Simulations. The protein's C-terminus is fixed using a harmonic potential, while a pulling force is applied to the N-terminus along the z-axis at a rate of 0.1 nm/ns, inducing unfolding. The force-bearing β -strands (shown in yellow) undergo shear unfolding first.

Fig. 5.

Fig. 5 AFM-SMFS Results of Titin I27 and A-series. **a**, From top to bottom, the protein structures of the I27 and SuperMyo A series proteins (A25, A218, A339) are shown. The yellow regions represent the force-bearing β -strands, with the main chain hydrogen bonds indicated by blue lines. **b**, For each protein, three representative force curves are shown, with the red portions representing the unfolding events of the proteins. **c**, The statistical histogram of the unfolding forces for the corresponding proteins. **d**, The statistical histogram of the ΔLc during protein unfolding.

Fig. 6.

Fig. 6 AFM-SMFS Results of B-series. **a**, From top to bottom, the protein structures of the SuperMyo B series proteins (B42, B347, B501) are shown. The yellow regions represent the force-bearing β -strands, with the main chain hydrogen bonds indicated by blue lines. **b**, For each protein, three representative force curves are shown, with the red sections representing the unfolding events of the proteins. **c**, The statistical histogram of the unfolding forces for the corresponding proteins. **d**, The statistical histogram of the ΔLc during protein unfolding.

Fig. 7.

Fig. 7 AFM-SMFS Results of C-series. **a**, From top to bottom, the protein structures of the SuperMyo C series proteins (C92, C328, C352) are shown. The yellow regions represent the force-bearing β -strands, with the main chain hydrogen bonds indicated by blue lines. **b**, For each protein, three representative force curves are shown, with the red sections representing the unfolding events of the proteins. **c**, The statistical histogram of the unfolding forces for the corresponding proteins. **d**, The statistical histogram of the ΔLc during protein unfolding.

Fig. 8.

Fig. 8 AFM-SMFS Results of D-series. **a**, the protein structures of the SuperMyo D397 and D399 are shown. The yellow regions represent the force-bearing β -strands, with the main chain hydrogen bonds indicated by blue lines. **b**, For each protein, three representative force curves are shown, with the red sections representing the unfolding events of the proteins. **c**, The statistical histogram of the unfolding forces for the corresponding proteins. **d**, The statistical histogram of the ΔLc during protein unfolding. **e**, Represents the structures of D300, which failed to express.

Fig. 9.

Fig. 9 AFM-SMFS Results of E389. **a**, the protein structures of the SuperMyo E57 and E389 are shown. The yellow regions represent the force-bearing β -strands, with the main chain hydrogen bonds indicated by blue lines. **b**, For each protein, three representative force curves are shown, with the red sections representing the unfolding events of the proteins. **c**, The statistical histogram of the unfolding forces for the corresponding proteins. **d**, The statistical histogram of the ΔLc during protein unfolding. **e**, represents the structure of E203, which failed to express.

Fig. 10.

Fig. 10 AFM-SMFS Results of F553. **a**, the protein structures of the SuperMyo F553 are shown. The yellow regions represent the force-bearing β -strands, with the main chain hydrogen bonds indicated by blue lines. **b**, For each protein, three representative force curves are shown, with the red sections representing the unfolding events of the proteins. **c**, The statistical histogram of the unfolding forces for the corresponding proteins. **d**, The statistical histogram of the ΔLc during protein unfolding. **e** and **f** represent the structures of F422 and F600, respectively; both proteins failed to express.

Fig. 11.

Fig. 11 RMSD analysis of SuperMyo in Annealing Simulations. During the 1000 ns annealing MD simulation, the temperature gradually increased from 0 K to 413 K, and the structural changes of SuperMyo throughout this process can be reflected in the RMSD values.

Fig. 12.

Fig. 12 Schematic of Protein Heating Experiment. The protein sample is placed in a PTFE-lined high-pressure reactor and heated in an oven to temperatures above 100°C (121°C or 150°C). Temperature-sensitive paper is placed inside the reactor to ensure the target temperature is reached.

Fig. 13.

Fig. 13 CD Experiments of Mechanical Proteins After Heat Treatment. a, CD results of untreated SuperMyo at 25°C. **b,** CD results of proteins after 10 cycles of heating from -196°C to 121°C. From right to left are A339, B42 and C352. **c,** CD results of proteins after heating at 150°C. From right to left are A339, B42 and C352.

Fig. 14.

Fig. 14 Force Spectroscopy Experiments of SuperMyos After 150°C Heat Treatment. **a**, The left panel shows the typical force curves of SuperMyo A339 after 150°C heating. The middle panel displays the corresponding unfolding force histogram. The right panel presents the ΔLc histogram. **b** and **c** show the force spectroscopy results for B42 and C352, respectively.

Table 1. Statistics of Mechanical Properties of SuperMyo Proteins

Name	H-bonds	SMFS (10^3 nm/s)				MW (kDa)	SMD (10^8 nm/s)	
		Force (pN)	Ave. LR (pN/s)	Δ Lc (nm)	n		Force (pN)	Ave. LR (pN/s)
I27	4	246 $\pm$ 2	2 $\times 10^4$	27.8 $\pm$ 0.1	324	9.8	996	5 $\times 10^{10}$
A25	8	342 $\pm$ 2	2 $\times 10^4$	44.0 $\pm$ 1.6	205	13.9	1371	3 $\times 10^{10}$

B42	13	431 $\pm$ 1	3 $\times 10^4$	32.4 $\pm$ 0.1	488	11.7	1390	7 $\times 10^{10}$
B347	13	427 $\pm$ 1	3 $\times 10^4$	31.4 $\pm$ 0.1	531	11.7	1373	1 $\times 10^{11}$
B501	13	372 $\pm$ 2	3 $\times 10^4$	32.5 $\pm$ 0.2	201	10.8	1409	7 $\times 10^{10}$
C92	15	443 $\pm$ 1	3 $\times 10^4$	51.9 $\pm$ 0.1	773	15.6	1596	5 $\times 10^{10}$
C328	18	412 $\pm$ 2	3 $\times 10^4$	51.4 $\pm$ 0.1	277	16.0	1627	5 $\times 10^{10}$
C352	18	559 $\pm$ 2	5 $\times 10^4$	50.8 $\pm$ 0.05	891	16.1	1618	5 $\times 10^{10}$
D397	23	669 $\pm$ 7	5 $\times 10^4$	66.1 $\pm$ 0.08	231	20.9	1821	6 $\times 10^{10}$
D399	23	744 $\pm$ 3	7 $\times 10^4$	65.4 $\pm$ 0.05	658	21.3	1974	4 $\times 10^{10}$
E57	28	763 $\pm$ 3	8 $\times 10^4$	68.2 $\pm$ 0.1	220	22.3	2045	6 $\times 10^{10}$
E389	28	839 $\pm$ 3	9 $\times 10^4$	69.0 $\pm$ 0.1	215	21.6	2038	5 $\times 10^{10}$
F553	33	1050 $\pm$ 6	1 $\times 10^5$	99.2 $\pm$ 0.1	317	29.0	2516	3 $\times 10^{10}$

Note: (1) The values for Force (pN) and Δ Lc (nm) are presented as mean $\pm$ SEM from Gaussian fitting. (2) LR represent force loading rate.

Table 2. Structure and NMR statistics of A339

Structure	A339
Distance restraints*	
NOEs	
Short range (intraresidue and sequential)	588
Medium range ($1 < i-j < 5$)	196
Long range ($ i-j \geq 5$)	165
Intermolecular	-
Hydrogen bonds	136
Dihedral angle restranints (ϕ and ψ)	215
Violations (mean and SD)	
Distance restraints (Å)	0.028±0.037
Dihedral angle restraints (°)	0.589±0.549
Structural coordinates rmsd	
Backbone atoms	0.49 Å
All heavy atoms	1.03 Å
Ramachandran plot	
Most-favored regions	99.7%
Additionally allowed regions	0.03%
Generously allowed regions	0.0%
Disallowed regions	0.0%

*The statistics apply to the 10 lowest-energy structures of each of the complexes.
