ABSTRACT

BACKGROUND

Misdiagnosis or underdiagnosis of rare diseases in patients with diagnoses of common diseases can lead to delayed or inappropriate treatments, thereby complicating the management of both rare and common conditions. Despite advances in molecular diagnostic techniques, the effect of rare diseases on the diagnosis of common diseases in research and clinical trials has not been comprehensively investigated.

METHODS

We used exome- and genome-sequencing data from participants in the U.K. Biobank, a research study, and five clinical trials involving patients who had received a primary diagnosis of multiple sclerosis, inflammatory bowel disease, or atopic dermatitis to assess the incidence of monogenic rare diseases that often manifest with clinical symptoms overlapping with those of these common diseases.

RESULTS

We identified 153 U.K. Biobank participants who carried a rare variant that contributes to a molecular diagnosis of a monogenic disorder — 53 of 1850 (2.86%) with a diagnosis of multiple sclerosis, 75 of 6681 (1.12%) with a diagnosis of inflammatory bowel disease, and 25 of 998 (2.50%) with a diagnosis of atopic dermatitis. We replicated the findings regarding such rare disease-causing variants in two independent cohorts — one including patients with a diagnosis of multiple sclerosis, and the other patients with a diagnosis of inflammatory bowel disease — who had undergone genome sequencing for research and for clinical trials, respectively. By combining genome and transcriptome analyses, we showed that molecular diagnosis can potentially elucidate mechanisms of inadequate response to therapeutic intervention.

CONCLUSIONS

Our study shows the value of systematic genome sequencing in understanding the phenotypic heterogeneity of common diseases and identifying failure to diagnose rare diseases and highlights the benefits of deep molecular phenotyping in clinical trials and patient care. ACCURATE AND TIMELY DIAGNOSIS IS crucial in health care because it explains a patient's health issue and guides treatment decisions. However, misdiagnoses have always affected the delivery of quality health care and continue to harm an unacceptable number of patients. It is estimated that 5% of U.S. adults who seek medical care each year receive a diagnostic error,¹ sometimes with severe consequences.² The adoption of high-throughput DNA-sequencing technology has dramatically increased the rate and speed of making a correct diagnosis, primarily in patients with cancer or rare or undiagnosed diseases,³ leading to notable improvements in clinical care.⁴

Ascertaining the root cause of a disease not only improves the ability to make a correct diagnosis but also is fundamental to the development of therapeutic or preventive measures. Patient recruitment for clinical trials typically depends on the clinical signs and symptoms of the disease under study, along with specific inclusion and exclusion criteria. Because of misdiagnosis or underdiagnosis, a small fraction of these patients might carry a rare variant capable of causing a monogenic disease that mimics the common disease under study. In addition, patients affected by both common and rare diseases might have more severe or different coexisting conditions. Consequently, a therapeutic agent targeting the underlying pathogenesis of a disease may not elicit a response in patients with a distinct disease mechanism, thus potentially affecting the study outcome.

Here, we investigated the presence of monogenic disease-causing variants within cohorts of patients with diagnoses of common diseases. We selected four common and complex diseases — multiple sclerosis, two inflammatory bowel diseases (Crohn's disease and ulcerative colitis), and atopic dermatitis — and tested for the co-occurrence of rare diseases by identifying clinically defined molecular diagnoses of diseases that manifest with symptoms overlapping with those of each of these four conditions.

METHODS

DISEASE CASES AND COHORTS

The U.K. Biobank is a prospective, population-based cohort study involving more than 500,000

participants in the United Kingdom who were recruited between the ages of 40 and 69 years from 2006 through 2010. Health outcome data were obtained through links to electronic health records (inpatient hospital records in the Hospital Episode Statistics database and primary care [general practitioner] records) and cancer and death registries. Disease cases were identified with the use of diagnosis codes from the *International Classification of Diseases* (ICD), which were recorded by clinical coders on the basis of patient medical notes from their hospital stay. Cases of multiple sclerosis and inflammatory bowel disease were ascertained with the use of both the 9th and 10th revisions of the ICD. Atopic dermatitis cases were defined by a combination of the ICD codes and a history of topical glucocorticoid treatment for atopic dermatitis. Details regarding sequencing and analysis of U.K. Biobank exomes⁵ are included in Supplementary Appendix 1, available with the full text of this article at NEJM.org.

Because the disease diagnoses in the U.K. Biobank cohort were extracted from electronic health records, there is a risk of misdiagnosis due to administrative errors, such as disease misclassification, or a lack of specific ICD codes for some rare diseases identified in our study. Moreover, rare disease-associated variants discovered in clinical studies (i.e., in participants specifically recruited for gene discovery purposes) often show incomplete penetrance or variable expressivity in the general population.⁶ Therefore, we regarded the U.K. Biobank cohort as a discovery cohort and went on to test for the presence of monogenic disease-causing variants in follow-up cohorts comprising participants recruited for research (the Genuity Science cohort of patients with multiple sclerosis) and for the clinical trials in inflammatory bowel disease. These participants underwent more rigorous phenotyping than the U.K. Biobank participants and were thus evaluated as follow-up cohorts.

The Genuity Science cohort of persons with multiple sclerosis had undergone genome sequencing by Genuity Science. A total of 2025 participants in Ireland and 5450 in the United Kingdom were recruited prospectively from neurology clinics or retrospectively from existing biobanks. All were adults (≥18 years of age at the

time of diagnosis), and their diagnosis was made by trained neurologists on the basis of the revised McDonald criteria of 2013.⁷ Clinical data were extracted and curated through retrospective medical record reviews by trained health care professionals. Participants with diagnoses of other conditions that may cause neurologic symptoms similar to those of multiple sclerosis, such as Sjögren's syndrome, hereditary myelopathies, brain tumors, and structural damage to the brain or spinal cord, were excluded from recruitment.

An additional follow-up cohort comprised participants from five clinical trials of treatment for inflammatory bowel disease (Crohn's disease or ulcerative colitis). The SERENE trials were two phase 3, multicenter, double-blind, randomized clinical trials that were conducted in parallel to evaluate the efficacy of more intensive as compared with standard induction and maintenance dose regimens of adalimumab (an anti-tumor necrosis factor α [anti-TNF- α] antibody) for the treatment of Crohn's disease (the SERENE CD trial)⁸ and ulcerative colitis (the SERENE UC trial).⁹ At enrollment, all the participants had a diagnosis of moderate-to-severe, active Crohn's disease or ulcerative colitis, made by trained gastroenterologists. Pediatric patients were excluded, and the age of the participants at baseline ranged from 18 to 75 years. Among the SERENE trial participants, genome sequencing was performed in 293 with Crohn's disease and in 275 with ulcerative colitis, who were selected on the basis of a variable response to treatment (see the Supplementary Methods in Supplementary Appendix 1). The other three trials (also phase 3) assessed the efficacy and safety of upadacitinib (an oral selective Janus kinase 1 inhibitor) for ulcerative colitis¹⁰ and of risankizumab (an interleukin-23 inhibitor) for Crohn's disease¹¹ and ulcerative colitis.¹² Among these trial participants, exome sequencing was performed in 287 with Crohn's disease and in 625 with ulcerative colitis.

Our study was funded by AbbVie, which participated in the design and conduct of the study, the interpretation of data, and the review and approval of the manuscript for submission. The authors vouch for the accuracy and completeness of the data, and written informed consent was obtained from all the participants.

ASSEMBLY AND ANALYSIS OF GENE PANELS FOR MONOGENIC DISEASES

Monogenic disease genes were compiled with the use of broad definitions that capture the most commonly recognized clinical symptoms of multiple sclerosis, inflammatory bowel disease, and atopic dermatitis. The PhoRank gene-ranking algorithm, implemented in VarSeq software, version 2.2.5 (Golden Helix), was used to build three gene panels, one for each disease. This algorithm ranks genes on the basis of their relevance to user-specified phenotypes as defined according to the Human Phenotype Ontology (HPO, a standardized vocabulary of phenotypic abnormalities encountered in human diseases¹³) and Gene Ontology biomedical terminology.¹⁴ For each of the common diseases, we used two HPO terms — HP:0002715 (abnormality of the immune system) and HP:0000707 (abnormality of the nervous system) for multiple sclerosis, HP:0002715 and HP:0004386 (gastrointestinal inflammation) for inflammatory bowel disease, and HP:0002715 and HP:0000951 (abnormality of the skin) for atopic dermatitis. These queries yielded 1973 genes for multiple sclerosis, 1285 genes for inflammatory bowel disease, and 2385 genes for atopic dermatitis; the associations of these genes with monogenic diseases were further refined by manual curation with the Online Mendelian Inheritance in Man database.¹⁵ Mitochondrial genes, nondisease genes, and genes associated with multifactorial or infectious diseases or with unknown inheritance were excluded. The remaining 1673 genes (for multiple sclerosis), 1044 genes (for inflammatory bowel disease), and 1500 genes (for atopic dermatitis) were used for pathogenic variant screening. For each of the three gene panels, we queried the exome-sequencing data in the discovery cohort (U.K. Biobank) and the follow-up cohorts for rare variants with allele frequencies of less than 1% in the entire dataset (Fig. 1). Allele frequencies were calculated with the SeqArray R package, version 1.35.7.¹⁶ Next, we attempted to assign pathogenicity to these variants and determine their associations with known monogenic diseases in accordance with variant-classification guidelines recommended by the American College of Medical Genetics and Genomics (ACMG).¹⁷ Variant pathogenicity was assessed with VarSeq software, version 2.2.5.

For gene nomenclature, we used the Human Genome Organisation Gene Nomenclature Committee–approved symbols and all known aliases, which are shown in Tables S1, S2, and S3 (Tables S1 through S18 are provided in Supplementary Appendix 2).

STATISTICAL ANALYSIS

In the analysis of coexisting conditions, Fisher's exact test was used to assess the significance of associations between ICD codes, with odds ratios calculated to determine the strength of these associations. The analysis was conducted with the "stats" package in R software, version 4.2.0. Age-Related Multiple Sclerosis Severity (ARMSS) scores were compared between persons carrying pathogenic variants and noncarriers with the use of a one-tailed Wilcoxon rank-sum test (see the Supplementary Methods). To

account for potential confounders, we also evaluated the association between ARMSS score and pathogenic-variant carrier status using linear regression models. ARMSS values were transformed into z scores to ensure a normal distribution, and the association between pathogenic-variant carrier status and ARMSS score was tested, with adjustment for age and sex.

RESULTS

DISEASE COHORTS

We evaluated 9529 participants with sequencing data from the U.K. Biobank (1850 with a diagnosis of multiple sclerosis, 6681 with a diagnosis of inflammatory bowel disease, and 998 with a diagnosis of atopic dermatitis), 7475 participants from Ireland and the United Kingdom with a diagnosis of multiple sclerosis in the Genuity

Science cohort, and 1480 participants from five clinical trials in inflammatory bowel disease (580 with Crohn's disease and 900 with ulcerative colitis) — a total of 18,484 participants (Table S4). The representativeness of the study participants relative to those in the broader population affected by multiple sclerosis, inflammatory bowel disease, or atopic dermatitis is shown in Table S5.

MISDIAGNOSED OR UNDERDIAGNOSED RARE DISEASES IN THE U.K. BIOBANK COHORT

Among the U.K. Biobank participants with a diagnosis of multiple sclerosis, inflammatory bowel disease, or atopic dermatitis, we identified 153 (1.61%) who carried a molecular diagnosis for a mendelian disease. Multiple sclerosis is typically diagnosed through clinical, radiologic, and laboratory assessments. However, several rare diseases or syndromes may resemble multiple sclerosis. As a consequence, occasional misdiagnoses of multiple sclerosis have aroused concerns for patient care.¹⁸ Among 1850 U.K. Biobank participants with a diagnosis of multiple sclerosis, we identified 52 rare pathogenic or likely pathogenic variants in 34 genes in 53 participants (2.86%) (Fig. 1); these genes have been linked to a number of mendelian disorders (Table S6). Among the identified variants, 47 have been reported to be pathogenic in the literature. The remaining variants were novel, and we classified them as likely pathogenic on the basis of the ACMG criteria.

One participant was heterozygous for the pathogenic *BICD2* p.Thr703Met variant, which is associated with congenital, autosomal-dominant spinal muscular atrophy.¹⁹ Two other participants carried variants causative of autosomal-dominant familial amyotrophic lateral sclerosis: p.Gly38Arg²⁰ in *ANXA11* and p.Thr622Ala²¹ in *MATR3*. The highest number of pathogenic variants, 11 in 13 unrelated persons, were found in *NOTCH3*, which is linked to the autosomal-dominant cerebral arteriopathy and subcortical infarct leukoencephalopathy (CADASIL). There have been numerous instances of CADASIL being misdiagnosed as multiple sclerosis on the basis of radiological findings of confluent white-matter changes.^{22–26}

Our findings indicate that some U.K. Biobank participants with rare diseases might have received a misdiagnosis of multiple sclerosis or

that certain rare diseases were underdiagnosed in participants with a diagnosis of multiple sclerosis. These misdiagnoses and underdiagnoses may have been due to overlapping symptoms or the phenotypic variability of multiple sclerosis, which became clear when we compared the complete electronic health records of persons with rare disease-causing variants with those without such variants, uncovering cases with severe coexisting conditions not typically expected in patients with multiple sclerosis. For instance, we observed a substantial enrichment of dementia (odds ratio, 14.79; $P=0.002$) and convulsion (odds ratio, 3.54; $P=0.002$) among participants with rare disease-causing variants (Table S7). These findings show that in addition to misdiagnosis, rare diseases can also exacerbate common disease symptoms when they co-occur.

Sporadic inflammatory bowel disease is a complex condition influenced by genetic and environmental risk factors and typically shows polygenic inheritance. However, there are also inherited forms of inflammatory bowel disease, with more than 100 genes linked to monogenic disease.²⁷ Many of these monogenic conditions do not respond to standard therapies and are associated with high morbidity and mortality.²⁸ Therefore, an accurate diagnosis for these patients is crucial for providing effective medical care and determining their eligibility for clinical trials. Among 6681 U.K. Biobank participants with diagnosis codes for inflammatory bowel disease, we identified 54 rare pathogenic or likely pathogenic variants in 30 genes in 75 participants (1.12%) (Fig. 1 and Table S8). Several genes stood out as having an excess of pathogenic or likely pathogenic variants, such as *TNFRSF1A* and *TNFRSF13B*. For example, one third of these participants (25 of 75) carried pathogenic or likely pathogenic variants in *TNFRSF13B*, which is associated with common variable immunodeficiency.^{29,30}

Finally, among 998 U.K. Biobank participants with a diagnosis of atopic dermatitis, we identified 18 pathogenic or likely pathogenic variants in 13 genes in 25 participants (2.50%) (Fig. 1 and Table S9). As has been reported previously,³¹ *FLG*, the gene encoding the filaggrin protein, was frequently mutated in persons affected by atopic dermatitis. Loss-of-function variants in *FLG* cause the severe, rare skin condition called

ichthyosis vulgaris.³² We found that 8 participants carried biallelic loss-of-function variants in *FLG*, including 4 homozygous participants and 4 participants with two different loss-of-function variants. Directly determining the chromosomal phase in these 4 participants was not possible owing to the physical distance between the variants and the limitations of short-read sequencing technology. Nevertheless, on the basis of maximum-likelihood estimates, these variants are predicted to segregate in trans (Fig. S1 in Supplementary Appendix 1).³³ Furthermore, in 2 participants, we identified two ultrarare, pathogenic *PTPN11* variants (p.Gly60Ala and p.Gln256Arg) that were previously associated with Noonan's syndrome, a rare disorder that can cause dry skin.

To date, at least 12 genes have been implicated in Noonan's syndrome.³⁴ To better understand the extent of underdiagnosis of Noonan's syndrome in the general population, we screened for these 12 genes among the U.K. Biobank participants and conducted a comprehensive analysis of coexisting conditions using electronic health records from the carriers of pathogenic or likely pathogenic variants (see the Supplementary Methods). We identified 164 persons who were probably affected by Noonan's syndrome and clinically related disorders; however, only 5 of the 73 participants for whom we had general practitioner records had a formal diagnosis of Noonan's syndrome (Table S10). Most of the participants received a diagnosis of either related symptoms or different diseases (Table S11). Although Hospital Episode Statistics records are accessible for the entire U.K. Biobank cohort, general practitioner records are currently available for 45% of the cohort. Among the remaining 91 participants without a diagnosis of Noonan's syndrome in the Hospital Episode Statistics records, it is unclear whether a diagnosis exists in their general practitioner records, although it seems likely that a small proportion would have one documented. As a hallmark of Noonan's syndrome, the average standing height of both male and female participants was significantly lower than the average height in the entire U.K. Biobank cohort (Fig. S2). Although congenital malformations were reported in 13% of these participants, disorders of bone density and structure were present in 17%, a finding suggesting that Noonan's syndrome-associated symptoms were captured to some extent.

RARE DISEASES IN THE GENUITY SCIENCE AND CLINICAL TRIAL COHORTS

In line with findings in the U.K. Biobank cohort, subgroups of participants with rare diseases in the Genuity Science research cohort and the clinical cohorts were identified. In the Genuity Science multiple sclerosis cohort, 88 participants (1.18%) had a potential molecular diagnosis for a rare disease (Table S12). Although there were four times as many participants in the Genuity Science cohort (7475 participants) as in the U.K. Biobank cohort (1850 participants), the proportion carrying pathogenic variants was less than half that in the U.K. Biobank cohort (2.86%). This difference might be related to electronic health record–based diagnosis in the U.K. Biobank cohort, as compared with targeted phenotyping in the Genuity Science cohort, in which the participants with suspected rare diseases were mostly excluded.

Furthermore, to determine whether rare diseases had an effect on the severity of multiple sclerosis, we calculated the ARMSS score in 31 carriers of pathogenic variants and 3158 noncarriers with available data (see the Supplementary Methods and Table S13). We found that participants carrying pathogenic or likely pathogenic variants had higher ARMSS scores than those without such variants ($P=0.02$) (Figs. S4 and S5).

Among 1480 participants with sequencing data in the inflammatory bowel disease clinical trials cohort, we identified 70 (4.73%) who had a molecular diagnosis of a rare disease (Table S14). The higher fraction of rare diseases identified in this cohort than in the U.K. Biobank cohort (1.12%) may be attributed to the targeted recruitment of patients with moderate-to-severe inflammatory bowel disease, in whom the condition may have developed owing to highly penetrant, rare variants. Similar to the findings in the U.K. Biobank, the findings among participants in the clinical trials showed that a majority (39 of 70) carried pathogenic variants in *TNFRSF13B*, which suggests that common variable immunodeficiency caused by pathogenic *TNFRSF13B* variants is probably misdiagnosed as inflammatory bowel disease or primarily manifests with inflammatory bowel disease–like symptoms.³⁵ Consistent with the hallmarks of *TNFRSF13B*-associated immunodeficiency, 3 of 5 participants with ulcerative colitis and 5 of 7

participants with Crohn's disease showed either extraintestinal manifestations or recurrent infections.

RARE DISEASE—CAUSING VARIANTS AND RESPONSE TO TREATMENT IN THE CLINICAL TRIALS COHORT

Of the 33 participants with a diagnosis of inflammatory bowel disease in the active treatment groups of the clinical trials of adalimumab who were found to carry rare disease-causing variants, 31 (94%) did not have clinical or endoscopic remission within a year. In the trial of upadacitinib in ulcerative colitis, which showed a 24 to 25% dose-dependent rate of endoscopic remission,¹⁰ 7 of 10 participants with rare disease-causing variants did not have endoscopic remission at week 8. Among these 7 participants, only 2 went on to complete the 52-week maintenance study but did not have endoscopic remission. These findings suggest that the distinct underlying molecular cause of the disease may have led to a lack of adequate remission in these cases. However, in the study of risankizumab in inflammatory bowel disease, which showed a 19 to 24% dose-dependent rate of endoscopic remission in Crohn's disease¹¹ and a 10.6 to 24.3% dose-dependent rate of endoscopic remission in ulcerative colitis,¹² 4 of 17 (23.5%) participants with rare disease-causing variants had endoscopic remission at the end of the 12-week induction period.

In support of the hypothesis that the distinct underlying molecular cause of the disease may have led to a lack of adequate remission in these cases, several signs of possible misdiagnoses were identified on retrospective medical history review of these participants. For instance, a female participant 60 years of age who had received a diagnosis of Crohn's disease and participated in the trial of adalimumab was heterozygous for a likely pathogenic variant (p.Arg148His) in the smooth-muscle actin gene *ACTG2*, which is associated with the autosomal-dominant familial visceral myopathy.³⁶ Abdominal pain, bowel obstruction, or gastroparesis, common in this condition, may have led to a misdiagnosis of Crohn's disease in this participant. Although the participant initially appeared to show clinical remission at week 12, she did not have endoscopic remission and did not show clinical or endoscopic remission by week 56.

Owing to the modest results for response to adalimumab treatment, with endoscopic remission reported in 26.2 to 28.6% of the participants at week 12 in the SERENE CD trial⁸ and in 10.0 to 13.1% of the participants at week 8 in the SERENE UC trial,⁹ and the low number of rare variant carriers among the participants who did not have remission, we were unable to estimate the statistical significance for nonresponse among the participants with rare diseases. However, we performed transcriptome analysis in the blood samples to assess the response to biologic treatment through an analysis of well-established inflammatory markers that are known to act downstream of TNF- α . The participants with rare variants in both the SERENE CD and UC trials showed minimal changes in gene expression (Tables S15 through S18). Although there was a high degree of overlap in the changes in gene expression over time between the participants with and those without rare disease-causing variants in both the SERENE CD and UC trials, those who had remission showed low-to-moderate changes in gene expression, whereas the participants who did not have remission showed very few changes, particularly in the SERENE CD trial. Enrichment of differentially expressed genes (false discovery rate, <0.05) in the analyses of change from baseline to week 12 (SERENE CD) or to week 8 (SERENE UC) suggested that inhibition of TNF- α signaling is unable to modulate pathways involved in primary immunodeficiency, B-cell receptor signaling, or TNF signaling in patients with rare disease-causing variants (Fig. 2).

DISCUSSION

It is estimated that collectively 4 to 6% of the general population are affected by some form of a rare disease.³⁷ Moreover, diagnosing rare diseases is a lengthy and stressful process that can take up to 7 years and involve up to eight physicians and two or three misdiagnoses. Heterogeneity of clinical symptoms is arguably the primary reason why many patients with rare disease remain without a diagnosis or have a misdiagnosis for years. The availability of electronic health records and sequencing data from nationwide biobanks provides an opportunity to revisit and estimate the number of persons with

Figure 2. Perturbed Pathways in Carriers of Rare Variants in the SERENE CD and UC Trials.

Shown are the topmost enriched pathways among the participants in the SERENE CD (Crohn's disease) trial⁸ (Panel A) and the SERENE UC (ulcerative colitis) trial⁹ (Panel B). Enrichment of KEGG (Kyoto Encyclopedia of Genes and Genomes) pathways was conducted on the basis of differentially expressed genes. Differential gene-expression analysis was performed with a linear mixed-effects model to assess changes in Crohn's disease from baseline to week 12 and in ulcerative colitis from baseline to week 8. In the analysis of the endoscopic remission (ER) end point, four different groups were considered, as shown in the heatmap columns: in the SERENE CD trial, these groups included the participants with remission (R) of Crohn's disease without any mutation (CD_NoMutation_ER_R), those with no remission (NR) of Crohn's disease without any mutation (CD_NoMutation_ER_NR), those with remission of Crohn's disease with mutation (CD_onlyMutation_ER_R), and those with no remission of Crohn's disease with mutation (CD_onlyMutation_ER_NR). Similar groups were compared for the participants in the SERENE UC trial. Genes that were differentially expressed were identified independently within each of the four groups on the basis of a false discovery rate (FDR)-adjusted P-value threshold of less than 0.05. Heatmap colors indicate significance levels in terms of $-\log_{10}(\text{FDR})$ -adjusted P values. Higher values indicate a higher level of significance, with larger $-\log_{10}(\text{FDR})$ values corresponding to lower FDR-adjusted P values (i.e., a higher level of significance). Gray indicates nonsignificance of the corresponding pathways. NF-κB denotes nuclear factor kappa light-chain enhancer of activated B cells, and TNF tumor necrosis factor.

rare conditions that were probably misdiagnosed or underdiagnosed in the general population. We conducted a proof-of-principle study using U.K. Biobank sequencing data and found variants that cause a broad range of rare mendelian diseases in persons with diagnoses of common diseases (Fig. 3). Although some of these rare diseases are incidental co-occurrences with the common diseases that we evaluated here, on the basis of phenotypic similarities and incidence, we conclude that many are probably misdiagnosed as a common disease. Furthermore, misdiagnosis of monogenic diseases can have a profound effect on family members too. Identifying these rare diseases allows for genetic

counseling, which is crucial for guiding family members through cascade genetic testing and supporting their health decisions. However, caution is advised in counseling for adult-onset diseases with reduced penetrance and variable expressivity.

To replicate our U.K. Biobank findings, we screened participants in a research cohort and a clinical trials cohort for rare disease-causing variants. We identified persons with multiple sclerosis or inflammatory bowel disease who also had a molecular diagnosis of rare diseases, which corroborated our findings in the U.K. Biobank cohort. Among these three datasets and four types of diseases evaluated here, approxi-

mately 1 to 3% of persons carried pathogenic variants that cause rare diseases. However, in this study, we used samples that were convenient to obtain, focusing on diseases with large cohorts with clinical and genomic data. Our findings may be generalizable to other common conditions; if so, the extent could vary, depending on the phenotypic spectrum and disease severity.

In the inflammatory bowel disease clinical trials that we analyzed, many of the participants who did not have a response to treatment probably had a distinct genetic etiologic factor. Such rare disease–associated genes may offer insights into potential mechanisms of nonresponse, as we found in this study, and may help in the identification of novel therapeutic targets for inflammatory bowel disease. Conversely, some patients with rare diseases could present opportunities for drug repurposing when they have a serendipitous response to treatments in clinical trials. For example, in a trial of upadacitinib for rheumatoid arthritis,³⁸ we identified one patient with a known pathogenic *IFIH1* variant that causes the Aicardi–Goutières syndrome who had a favorable response profile. Positive response to

JAK inhibition was observed previously in small, open-label trials involving patients with the Aicardi–Goutières syndrome.^{39,40} Because molecular diagnoses are not typically pursued for participants in large clinical trials, such happenstances often remain unidentified, and there are possibly many rare diseases that have missed treatment opportunities because of underdiagnoses or misdiagnoses. Therefore, prior knowledge of genetic defects or molecular phenotyping during a study should be integral to current clinical trial evaluations, as well as to future trial designs as genomic sequencing becomes more accessible before a trial begins.

Supplementary Methods

Exome sequencing of the U.K. Biobank samples

Exomes of the U.K. Biobank participants were sequenced at the Regeneron Genetics Center (RGC).¹ Data generation and quality control (QC) procedures were described previously.² QC steps, performed by RGC, included checks for sex discordance, contamination, unresolved duplicate sequences, and discordance with microarray genotype calls. Analyses for the present work were performed using the QC passed, filtered set of variants called the “Goldilocks” set, in 454,787 individuals, which includes 12.3M variants in 18,893 genes. Among these, approximately 1M are putative loss-of-function (pLoF) and 7.8M are missense variants, of which 1.8M (23%) were predicted to manifest damaging effects. Study participants who withdrew consent after completion of exome sequencing were excluded from the analysis. This research has been conducted using the U.K. Biobank Resource under application number 26041

Genome sequencing and analysis of the Genuity Science cohort samples

Genomic DNA from blood samples was extracted using the FlexSTAR+ system (AutoGen). The quality of genomic DNA (gDNA) was assessed using PicoGreen with the Varioskan LUX Multimode Microplate Reader, with an OD 260/280 ratio in the acceptable range of 1.8-2.1, and a DIN greater than 6.5 as determined by TapeStation. Samples that passed these QC assays proceeded to library preparation. Genome

sequencing libraries were prepared using the Illumina TruSeq DNA PCR-Free Library preparation kit and IDT (Integrated DNA Technologies) unique dual indexes. Library preparation was conducted in a Pre-PCR environment using the NGS STAR workstation (Hamilton). Following library preparation, the concentration of the libraries was quantified using the KAPA Library Quantification Kit (Roche) on a LightCycler instrument. Libraries were normalized based on the concentration determined from qPCR (225 pM). Libraries were sequenced to achieve a target mean coverage of 30×, with at least 95% of target bases covered at a minimum depth of 10×, using 150 bp paired-end reads on the Illumina NovaSeq 6000 platform with an S4 flow cell, following the manufacturer's protocol.

Raw sequencing FASTQ data were aligned to the GRCh38/hg38 reference genome build with the Burrows-Wheeler aligner³ and variants were called following the Best Practices workflow of the Genome Analysis Toolkit (GATK 3.8)⁴ implemented in the automated *Sentieon* pipeline (Sentieon). Single nucleotide variants (SNVs) and insertions/deletions (indels) were jointly called across all samples using the GATK HaplotypeCaller tool.⁵ Default filters were applied to SNV and indel calls using the Variant Quality Score Recalibration (VQSR) tool⁶. Variant annotations were performed using Variant Effect Predictor (VEP).⁷ Stringent QC measures were implemented, including confirmation of sex concordance and concordance with microarray genotyping data. Discordant samples were excluded from downstream analyses.

Genome sequencing of inflammatory bowel disease clinical trial samples

Genomes of 568 subjects participated in the SERENE clinical trials were sequenced at Washington University in St. Louis. Sequencing libraries were prepared using the automated Kapa PCR-free kit. Libraries were sequenced in 150 bp paired-end reads on the Illumina NovaSeq 6000 platform using the S4 flow cell with an average depth of 30×. Analysis ready sequence data were created using best practices with the *Sentieon* suite release 201911 (Sentieon). Briefly, alignment was performed using the bwa-mem algorithm. Duplicate reads were marked and removed, base quality scores were recalibrated, and then genotypes were called at the individual level using HaplotypeCaller.⁵ This was followed by joint genotype calling using the GVCFTyper

algorithm. Following genotype calling, variant quality scores were generated using variant quality score recalibration, run separately for single nucleotide variants (SNVs) and indels with recommended parameters and reference data.⁶ Variants were annotated using VEP (v99.2; cache version 99).⁷

Comorbidity analysis in the U.K. Biobank

Record-level, hospital inpatient diagnosis data (HESIN_DIAG) were downloaded from the U.K. Biobank Research Analysis Platform (DNAnexus) on May 10th, 2023. Data on hospital inpatient admissions are provided to the U.K. Biobank by the Data Access Request Service of National Health Service (NHS) England for England, by the Secure Anonymized Information Linkage Databank at the University of Swansea for Wales, and by Public Health Scotland for Scotland. Records date back to 1997 for England, 1998 for Wales and 1981 for Scotland. All clinical data in the hospital inpatient data are coded according to the World Health Organization's ICD (International Classification of Diseases and Related Health Problems). English and Welsh hospital data are coded in ICD-10. Because the collection of Scottish data began earlier (in 1981), data collected prior to 1997 are coded in ICD-9. For the comorbidity analysis, a 2 × 2 contingency table was created for each ICD code. The table contained counts of participants with and without that code in their health records and participants classified by their inclusion in the target or background cohort. Fisher's exact test was used to calculate the significance of the association for each code, and the odds ratio was calculated to determine the strength of the association. The analysis was performed using the *stats* library in R (4.2.0). Significance level and odds ratio were obtained using *fisher.test* function and were adjusted using *p.adjust* function and the *fdr* method.

Calculation of multiple sclerosis disability scores

From an initial cohort of individuals who underwent genome sequencing, we restricted the analysis to the 3,189 with a) an Expanded Disability Status Score (EDSS) and b) a recorded age at the time of the score. We calculated the Age-Related Multiple Sclerosis Severity Score (ARMSS) based on these parameters. Demographic characteristics of

the included cohort, stratified by pathogenic variant carrier status, is shown in Table S13. Of the 3,189 individuals, 31 (0.97%) were found to carry a pathogenic variant.

ARMSS is a normalized physical disability metric which accounts for the monotonic effect of increasing age on physical disability in multiple sclerosis.⁸ As disability increases with age, the ARMSS estimates an individual's deviation from their 'expected' level of disability at any given age, and thus allows a cross-sectional estimate of an individual's disability over time and a comparison between individuals of different ages. The ARMSS is similar conceptually to the Multiple Sclerosis Severity Score (MSSS), which accounts for disease duration rather than biological age.⁹ Age is typically more readily available and less prone to recall bias than disease duration, and so the ARMSS is a more practical choice in most large cohort settings.¹⁰ The ARMSS was derived using the *ms.sev* R package by ranking each individual's EDSS against others in the same 2-year age bin from the reference dataset.⁸ The proportional rank is then converted to a scale from 0-10 to reflect the original EDSS scale. Formally the ARMSS score is derived as:

$$\text{ARMSS} = \frac{\text{EDSS rank within 2 year age bin}}{\text{N of patients in age bin} + 1} \times 10$$

Figure S3 shows the relationship between age, EDSS, and the ARMSS, highlighting the point that individuals with an unexpectedly high EDSS for their age will have a high ARMSS, and vice-versa.

Comparison of multiple sclerosis disability in pathogenic variant carriers

To test the hypothesis that multiple sclerosis cases who harbored pathogenic variants may have more severe disease, we first performed a one-tailed Wilcoxon Rank Sum test, which confirmed higher ARMSS (disability scores) in the pathogenic carriers (one-tailed $P = 0.02151$, two-tailed $P = 0.04302$). We observed the same result for both the unadjusted EDSS (one-tailed $P = 0.02655$) and the MSSS (one-tailed $P = 0.044$), but no association with age of onset (two-tailed $P = 0.7564$), nor with the proportion of PPMS cases (Fisher's exact $P = 1$). To account for confounding we tested this observation

using linear regression models. We first transformed the ARMSS score by Z-scoring to ensure this variable was normally distributed. In a model adjusted for age and sex, the association between pathogenic carrier status and ARMSS score persisted ($P = 0.04$); carriage of a pathogenic variant was associated, on average, with a 0.4-SD increase in the ARMSS ($\beta = 0.37$, 95% CI 0.02 - 0.72)

Gene expression analysis

RNA sequencing of poly(A)-selected RNA samples, isolated from whole blood, was performed in 76bp single-end Unique Molecular Identifier (UMI)-tagged reads. Average number of unique reads were 20.6M and 15.2M in SERENE-UC and SERENE-CD studies, respectively. In the SERENE-UC study, 1,098 samples were collected from 294 patients at baseline and weeks 2, 4, and 8, while in the SERENE-CD study, 1,086 samples were collected from 277 patients at baseline and weeks 2, 4, and 12. Gene expression changes were evaluated in patients with and without rare pathogenic variants separately in all patients at different time points.^{11,12} Change-from-baseline analyses were performed for both sets of patients. Similar analyses were conducted for remitters and non-remitters under clinical and endoscopic endpoints. For gene expression changes, linear mixed-effect models were fitted with Benjamini–Hochberg method-based correction for multiple testing.¹³ Fisher’s exact test-based overrepresentation analysis was conducted for pathway enrichment using the KEGG database.¹⁴

Figure S2: Distribution of standing heights of subjects with Noonan-like syndrome compared to the rest of the U.K. Biobank cohort. Standing height of male (n=90) and female (n=73) cases and controls (227,498 males and 271,930 females) was measured using a Seca 202 device at the time of initial assessment visit. Height measurement was not available for one male case.

Figure S3: Relationship between age at disability score and disability score in individuals with multiple sclerosis in the Genuity Science cohort. The figure illustrates the generally monotonic relationship between age and disability. Points are colored with the ARMSS, an age-adjusted disability metric that standardizes an individual's disability score to the expected score for their age. Points in the top left-hand corner of the plot reflect people with unexpectedly high disability for their age, and hence a high ARMSS, whereas points in the bottom right reflect people with an unexpectedly low score (i.e. minimal disability) despite their older age.

Figure S4: Violin plots with nested boxplots showing the relationship between pathogenic variant carrier status and ARMSS. Multiple sclerosis cases in the Genuity Science cohort carrying a putative pathogenic variant tend to have higher disability scores.

Figure S5: Distribution of ARMSS in pathogenic variant carriers divided according to the gene in which their variant was detected. Cases are grouped by the mutated gene when there is more than one case per gene. The rest of the cohort is included in the left-most part of the plot ('No pathogenic variant'). Individual data points are not shown as the number of cases for each of the genes was less than 10.

Description

Multiple Sclerosis (MS), Inflammatory Bowel Disease (IBD), Atopic Dermatitis (AtD)

MS: MS is 2-3 times more common in females than in males.

IBD: Crohn's disease (CD) affects men and women at similar rates. Some studies suggest a slight female predominance in some regions, but the differences are not substantial. Ulcerative colitis (UC) also affects both sexes, but there is a slight predominance in males. However, this pattern can vary geographically.

MS: MS is frequently diagnosed between the ages of 20 and 40, with an average age of onset around 30 years. It is rare in children.

IBD: IBD often begins in the late teens to early 30s, with a peak incidence between the ages of 15 and 30. There is a secondary, smaller peak in incidence around the ages of 50 to 60. In males, particularly in the younger age group. Females often experience onset at a slightly younger age. There are no significant differences between sexes.

UKB: UKB participants were 40-69 years of age when they were recruited to the study, therefore the M does not represent pediatric patients affected by any of these diseases.

Clinical Trials: The IBD clinical trials include only adult patients above 18 years of age. This cohort also does not include children.

MS: MS is most common in individuals of Northern European descent. Therefore, both the UKB and Genuity Science cohorts are broader affected Northern European populations.

IBD: IBD is most prevalent in individuals of European descent. This group tends to have the highest rates of IBD, and lifestyle factors common in Western countries. Ashkenazi Jews are known to have a significantly higher risk of IBD than other groups. This increased risk is largely attributed to genetic factors specific to this population. IBD was the most common in this group. However, recent studies indicate increasing rates of both CD and UC, suggesting that the prevalence may be increasing. Prevalence among Hispanic/Latino individuals is generally lower than in Europeans. However, variation in prevalence is increasing, likely due to changes in environment and diet. IBD was once rare in Asian countries, but its prevalence is increasing with lifestyle shifts toward Western diets. This trend is especially noted in East Asian countries. There is also an increase in IBD in American populations, and it is generally thought to be lower compared to other groups. However, more research is needed.

AtD: Atopic dermatitis is quite common in European populations. However, African Americans tend to have higher rates of AtD compared to Europeans. Additionally, AtD can be more severe and persistent in African American individuals. Features, such as papular lesions and lichenification. The prevalence of AtD in Asian and Pacific Islander populations is lower. Differences in the skin manifestation and disease course compared to European populations. Prevalence of AtD varies among some studies suggesting higher rates in Caribbean and South American subgroups. The presentation of AtD is influenced by genetic and environmental factors. Data among Indigenous and Native populations are limited, but the prevalence is thought to be higher.

MS: MS prevalence is generally higher in countries located farther from the equator. This includes regions in North America, the United States, and parts of Australia and New Zealand. The prevalence in these areas is often attributed to higher levels of vitamin D. Countries closer to the equator, such as many in Africa, Asia, and South America, have lower prevalence. The reasons are not entirely understood but may be linked to genetic factors, sunlight exposure, and infection. MS prevalence even within their borders. For example, the northern parts of the United States and Canada have higher prevalence than southern regions.

IBD: IBD is more common in North America, Northern and Western Europe, and Australia. These regions have higher prevalence rates, likely due to a combination of genetic susceptibility and environmental factors such as diet, lifestyle, and urbanization. There has been an increasing prevalence of IBD in developing regions, including parts of Asia, South America, and Africa. Factors such as urbanization, changes in diet (e.g., Westernization of diets), and improved healthcare systems that help in early diagnosis and treatment may be regional differences within countries, especially between urban and rural areas, with urban areas often having higher prevalence. Differences in lifestyle, environmental exposures, and healthcare access.

UKB: The UKB cohort is not completely representative of the general population, since there is evidence of selection bias. Nonetheless, while it is not suitable for estimating general disease prevalence or incidence rates, its large size and generalizable inferences about exposure-disease relationships (Fry et al. American Journal of Epidemiology 2019).
GS: The Genuity Science MS cohort consists of White European patients recruited at many sites across the United States. Therefore, this cohort does not represent non-European populations.

Clinical Trials: Clinical trials recruited patients with moderate to severe IBD. Therefore, patients in these studies are predominantly of European ancestry. More than 90% of participants in these studies are patients with European ancestry. These trials do not represent the general population of IBD patients.
